Middle adulthood is a developmental period covering the years from 35 to 65, with the core years between 40 and 60. The middle years have been neglected because developmental science and aging research often contrast younger with older adults and thus omit middle-aged adults (Lachman and Bertrand, 2001) (*see* Age Stratification). One reason for this neglect is that, traditionally, this period has been considered as a time of relative stability in many realms of life. Although this might hold true to some extent, middle adulthood is a challenging and complex period with manifold environmental and individual changes (Willis and Martin, 2005). Hence, understanding development in middle adulthood is important for several reasons. First, middle age is a unique period of the life span that is characterized by a complex interplay of multiple social roles. Middle-aged adults largely hold multiple roles with widest responsibilities, and the number and nature of these roles may change across midlife (Helson and Soto, 2005). Second, understanding middle adulthood is important because this period is characterized by a wide variability in its nature and course, as middle-aged adults show different developmental pathways. As such, it requires a focus on multiple trajectories of development and their interplay across different areas of life including family and work (Lachman, 2004). Third, development in earlier periods of the life span preceding midlife may influence psychological functioning in middle adulthood. As an example, research demonstrates that low self-esteem and decreases in self-esteem in adolescence predict individual differences in depression in the mid-thirties (Steiger et al., 2014). Therefore, identifying individual characteristics, sociocultural factors, and developmental antecedents of psychological functioning in middle adulthood is an important way to understand midlife development. Fourth, development in middle adulthood may have consequences for aging processes and coping in later years of the life span and therefore reflects an important developmental window into old age (*see* Retirement and Encore Adulthood: The New Later Life Course). For example, in middle adulthood it is possible to detect the first indications of developmental decline (Schaie, 2005). Knowledge of adaptive and maladaptive aging processes and midlife precursors of psychological functioning in old age is important to develop interventions to promote healthy aging and to prevent maladaptive processes.

Theoretical Perspectives

Several theoretical perspectives exist that specifically include middle adulthood as a distinct period of the life span (*see* Life Span Development, Theory of). For example, Erikson (1963) believes that a primary developmental challenge in middle adulthood is generativity, that is, one of contributing to society and helping to guide future generations (cf McAdams, 2001). According to Erikson (1963), development is the result of challenges and crises that typically occur in each life period. For example, young adults are exploring personal relationships and find intimacy in a long-term committed relationship, while failure may result in loneliness and isolation. In contrast, older adults tend to look back on their lives and feel satisfaction about their accomplishments or they experience many regrets about their life.

Middle-aged adults seek to make a positive contribution to the next generation through parenting, teaching, mentoring, leadership, creative activities, and contributions to leave a legacy for the next generation. Middle-aged adults give back to society through raising children, being productive at work, or becoming involved in community activities and organizations, such as caregiving to parents (Shifren, 2009). As such, they serve important roles in the family and relationships, at the workplace, and in the community and, more broadly, the society. They are often guides for the younger and older generations, with an ability to draw on their experiences in multiple domains (McAdams, 2001). Hence, when middle-aged adults sense that they have done nothing for the next generation, they develop a feeling of stagnation because they are dissatisfied with the relative lack of unproductivity (Erikson, 1963).

Other perspectives have been guided by theories of life span developmental psychology that views development as a lifelong process covering all periods of the life span including the middle years of adulthood (Baltes et al., 2006) (*see* Lifespan

Development, Theory of). These perspectives view midlife in the context of the entire life span rather than as a disconnected period (Staudinger and Bluck, 2001). They place emphasis on the potential plasticity of the midlife experience as a function of individual and environmental or contextual variables and compensatory behavioral changes to biological aging. Complex dynamic interactions between individuals and their environment are responsible for both gains and losses throughout middle adulthood (Baltes, 1987).

Maintenance and Adaptation Functions of Midlife

Middle adulthood is a relatively long time period that includes at least two transitions in which individuals are both leaving young adulthood and entering old age. Some researchers have suggested that distinguishing early, middle, and late periods of middle age would reflect the very different experiences, social roles, and health of adults in their 30s versus those in their 60s. One suggestion for such a categorization is based on the notion that resource investments and goal orientation across the life span differ with respect to three adaptive functions (Staudinger and Bluck, 2001). From childhood to young adulthood, *growth* is the primary function in the allocation of resources, whereas in old age the *management and prevention of losses* is predominate, as resources are increasingly needed to regulate losses such as by adjusting to chronic illnesses (cf Baltes, 1987).

Middle adulthood is primarily characterized by *maintenance* functions such as balancing family and career and the tendency to strive for stability (Staudinger and Bluck, 2001). Midlife also includes adaptation processes to the manifold and diverse life experiences of the middle years. However, according to these authors the investment of resources also differ across the middle-aged years, as considerable resources are still needed to invest in growth in early middle adulthood, while some resources are already needed to manage certain losses in late middle adulthood. As people move through the middle years, they encounter increasing, peaking, and decreasing opportunities to give back to society by striving for certain developmental goals and tasks, such as raising children or becoming established in a career and being productive at work (Havighurst, 1972).

A similar suggestion is based on the idea that important individual and environmental factors show peaks or valleys or even changes quality during middle adulthood (Helson et al., 2006). For example, social commitments and striving for status increase from young adulthood to early midlife and then decrease by late midlife, whereas the middle period is characterized by maximum status and responsibility in a socially complex environment (Helson and Soto, 2005).

Variability in Midlife Development

Although some theoretical perspectives on development during middle adulthood appear to describe normative development (e.g., Erikson, 1963; Havighurst, 1972), it is important to note that midlife development cannot be conceived as universal in nature. Middle adulthood is characterized by a wide variability in the nature and course of development (Lachman, 2004; Willis and Martin, 2005). That is, wide individual differences exist in how middle-aged adults' progress through the middle years (*see* Motivation: Life Course and Sociological Perspectives). For example, some people experience specific positive life events, such as becoming parents or getting a promotion at the workplace, whereas others are subject to negative life events, such as getting divorced or losing the job. Other people, in turn, report multiple events, whereas again others do not exhibit any major change in life circumstances in middle adulthood. As a result of diverse individual and environmental experiences in midlife each person may demonstrate a unique pattern of development.

Changes in the Environment

Middle adulthood is characterized by several changes in the environment. Changes may occur with respect to family, work and community contexts, social roles, transitions, life events, and circumstances.

Family, Relationships, Work, and Community

The primary social contexts or realms of experiences in middle adulthood are the family and the broader social network including diverse social relationships, the workplace, and the community (*see* Family as Institution; Wellbeing and Burnout in the Workplace, Psychology of). As noted earlier, middle-aged adults are motivated to give back to society through raising children, being productive at work, or becoming involved in community activities and organizations (Erikson, 1963). As such, social relationships are important in middle adulthood for several reasons. People are largely interested in positive interactions with other people, giving and receiving affection, and experiencing caring for others. However, the structure, nature, and functions of social networks may change across the middle years. For example, according to the social convoy model of social relations, people are accompanied from a dynamic social network of individuals such as the family members from whom they give and receive social support (Antonucci et al., 2011). The convoys are marked by stability and change, as some members of the convoy go, some stay, and new members come. In addition, the functions of social relationships may change in the middle years. For example, research demonstrates that the investments in meaningful social relationships increase with age, as people become more aware of the finiteness of opportunities (Charles and Carstensen, 2010).

The workplace is one of the primary settings of middle adulthood, and people's identity is largely defined by their work. In the middle years, most people attain their highest level of socioeconomic status along with widest responsibilities at work and/or in the family and community (Helson and Soto, 2005). The work context does not reflect a consistent and stable environment but rather a changing world. For example, technological advances, changes in social networking pattern inside and outside the workplace, and job characteristics are subject to change, which entails transitions in employment in coordination with changing family responsibilities, and later the experience of retiring. These work-related experiences might

also influence other domains of life such as family, leisure time, and finances (Lachman, 2004).

Occupational experiences may influence the individual and promote or prevent individual changes. At the same time, it is possible that individual characteristics may have an influence on work experiences as well. For example, research demonstrates that individual characteristics such as personality shape occupational experiences over time across middle adulthood, but occupational experiences have minimal impact on personality (Sutin and Costa, 2010). In summary, the family, relationships, the workplace, and community reflect key developmental contexts for the individual.

Multiple Social Roles and Responsibilities

Middle adulthood is a time when people are responsible members of the society and hold multiple roles with widest responsibilities in socially complex environments (Lachman, 2004). The primary social roles in middle adulthood are centered in family and relationships, work, and community. Family roles may be related to the family of origin (e.g., parents, grandparents, and relatives) and/or the family of destination (e.g., partner, children), whereas work and community roles relate to the career and the broader social environment, such as the community (*see* Family as Institution; Job Analysis and Work Roles, Psychology of). Furthermore, social roles tend to fall into two broad domains: Belongingness roles that contain friendships, family, and community roles, and status roles that contain work and social positions roles (cf Roberts and Wood, 2006). Different motivations underlie these two broad types of social roles. The desires to have family, close friendships, and to be integrated in a social group or social groups underlie belongingness roles, whereas the desires for social status, fame, money, and social regard are associated with status roles. Each social role includes a set of norms, internal and external social expectations, and expected behaviors that may have an influence on people. According to Roberts and Wood (2006), roles can serve as consistent subjective environments that people act within across time and situations. When people adapt a specific role, their experiences and behaviors may change, in particularly when they are highly committed and show a high investment to the social role (Lodi-Smith and Roberts, 2007).

Across middle adulthood, people have to coordinate multiple social roles (e.g., spouse parent, worker) (*see* Job Analysis and Work Roles, Psychology of). Sometimes middle-aged adults have to face different roles at the same time in different social situations, such as taking on a career, establishing a family, or taking care of parents, which might be a source of potential conflicts (Shifren, 2009). Moreover, many of the social roles are age graded. Social roles such as being a parent systematically change across the adult years (Helson and Soto, 2005). The number and the nature of these roles may change during middle adulthood. More specifically, the number of social roles increases from young adulthood to early midlife then decreases as children leave the parental home and adults approach retirement (Helson and Soto, 2005). In summary, it is during middle adulthood when the number of social roles peaks and then decreases and the role may change in character.

Transitions, Life Circumstances and Events

As people move through middle adulthood, they are faced with several transitions and changes in life circumstances. A typical transition in early middle adulthood is the transition to parenthood, which involves manifold physical, psychological, and social changes in the lives of the parents (Nazarinia et al., 2014) (*see* Transition to Adulthood; Fertility Theory). For example, the birth of a child is associated with changes in daily routines, activities, and sleep patterns. The transition to being a parent also reflects a change into a new social role that may trigger new experiences and behaviors (Roberts and Wood, 2006). Moreover, cultural specific timetables for events to occur (e.g., social clock) may influence the timing of transitions, such as having children. In later periods of midlife, parents may experience their adult children leaving home. The empty nest situation provides new role for the relationship with the partner.

Late-middle adulthood is also marked by the transition to retirement (Schultz and Wang, 2011) (*see* Retirement and Encore Adulthood: The New Later Life Course). This transition involves dramatic changes associated with work and social contacts and requires adaptation processes to the post-retirement life. Generally, transitions reflect challenges for the individual and the social environment including emotional difficulties. Yet, at the same time, they provide opportunities for change and growth to overcome routine and habit. Transitions may entail a reconsideration of values, priorities, and goals. For example, retirement may allow the retired individuals to pursue new interests and enjoy the freedom from daylong working.

During middle adulthood, some people experience profound changes in their life circumstances. Many life events may occur in midlife including acute illness, death of loved one, caring for one's parents, changes in relationships, loss of job, moving, changes in responsibilities at work, and financial difficulties. As an example, divorce is a life experience that is associated with a wide range of changes and might have several consequences for the divorcees. Indeed, studies reported a variety of economic, social, physical, and mental health consequences, although the full extent of such effects remains debated (Demo and Fine, 2010). Divorce is also associated with major changes and transitions with respect to role status. Consequently, changes in social roles might promote individual changes (Roberts and Wood, 2006). Specifically, new social roles such as being a single parent come with a new set of expectations and demands including parental responsibilities.

Unemployment and job loss in midlife are two other examples of life circumstances that may challenges people in middle adulthood. Possible consequences are the loss of income, independence, skills use, social contacts, and may challenge intimate relationships (*see* Unemployment and Mental Health). Because people's identity is largely defined by their work, a loss of job or unemployment is damage to social identity and status.

Another example relates to the fact that middle-aged people (the 'sandwich generation') sometimes have to care for ill parents and at the same time for demanding and challenging children or adolescents (Shifren, 2009). This double strain may be a source of chronic stress in midlife that requires an adaptive balance between parent care and employment and family roles.

People differ in how they interpret and understand stressful life events. For example, some people construe life events as turning points that reflect significant psychological changes in their lives. Another way to understand a stressful life event is to take a lesson away from experiences. How people interpret stressful life events may have an influence on themselves. For example, work shows that across middle adulthood, personality change might be more strongly related to how people understand the stressful events in their lives rather than simply the occurrence of such events (Sutin et al., 2010). For example, highly neurotic people might interpret an event as stressful whereas an emotionally stable person might see the same event as challenging but manageable. To summarize, diverse midlife experiences in terms of life circumstances and events contribute to wide variability in the nature and course of midlife development.

Changes in the Individual

In addition to environmental challenges, middle adulthood is characterized by individual changes. Changes may occur with respect to health and physical functioning as well as other domains of psychological functioning.

Health and Physical Changes

Middle adulthood is a time of relatively good self-reported health without dramatic changes, as compared to old age (Whitbourne, 2001). However, during midlife some people begin to show increases in health problems as well as gradual physical declines, particularly in late midlife. Examples for physiological changes that may occur refer to changes in the elasticity of the skin, changes in eyesight and in other sensory functions (e.g., hearing), back and joint pains, weight gain with related problems (e.g., cardiovascular disease and diabetes) (Whitbourne, 2001). In general, most of these health and physical changes do not cause disability or alter lifestyles of middle-aged adults. However, an accumulation of risk factors or risky health behaviors in middle adulthood may show negative effects later in life. For example, smoking, alcohol consumption, and overweight are risk factors for health in old age, whereas healthy lifestyles in midlife are preventive factors.

One major biosocial change in the middle years occurs in the area of reproduction, especially the menopause for women (*see* Fertility Theory; Fertility Theory: Theory of Life History Evolution). The menopause or climacteric occurs at some point between the ages of 46–58 years. It involves changes in hormonal levels and fertility and has effects on mood, and it is often associated with hot flashes, which generally last for a few months. However, women differ in their experiences of the menopause. The menopause often goes along with social changes that are typical of late-middle adulthood, such as children leaving home. For women, the menopause reflects an important biosocial transition, whereas men have no clear biosocial transition in middle adulthood.

Cognitive Abilities

Cognitive abilities are key competences that are needed to meet the challenges of job demands, education, and advanced training, societal expectations, and the demands of everyday life of middle-aged adults (Lachman, 2004) (*see* Modern Human Cognition, Evolution of). Middle adulthood provides many good opportunities for making intellectual contributions, given the position of middle-aged adults in the family, workplace, and society. Hence, middle age is the period of highest performance in a variety of individual domains. Middle-aged adults typically perceive themselves or are perceived by others as having not only more status and responsibility but also more effective intelligence and integrative skills (Lachman et al., 1994). The demands of status and widest responsibilities may encourage the development of these intellectual skills. For example, diverse work environments and workplace conditions may contribute to job-specific and individual differences in the development of cognitive abilities. As such, the development of cognitive abilities is more strongly influenced by environmental factors compared to other developmental periods (Sternberg et al., 2001).

As a consequence of diverse life contexts, changes in cognitive functioning in middle adulthood are varied and multidirectional (Schaie, 2005). Indeed, longitudinal research demonstrates that some aspects of cognitive functioning that depend on experience are maintained or even improved in midlife, while other aspects decrease (Willis and Schaie, 2005). For example, perceptual speed already begins to decline before the middle years. Number ability declines over middle adulthood and afterward. But the years from age 40 to the early 60s also reflect a period of maximum performance on some of the higher order abilities such as inductive reasoning and spatial orientation. These abilities then begin to show a decline in late-middle adulthood, though with many individual differences. As such, it is possible to detect the first indications of developmental decline in middle adulthood (Schaie, 2005).

Several risk factors or protective factors may contribute to the variability in cognitive development (Willis and Schaie, 2005). For example, multiple biosocial risk factors such as hypertension, diabetes, health status, cardiovascular disease, or stressful life circumstances may be associated to midlife cognitive decline. By contrast, several protective factors are associated with cognitive maintenance and plasticity. For example, high levels of education, complex environmental contexts and demanding activities at work, intellectual engagement with a wide range of interests, and high levels of exercise and physical activity are discussed as possible mechanisms than can be targeted in preventive interventions (cf Willis and Schaie, 2005).

Emotional Abilities

Emotions and emotional abilities are important to meet the challenges of social interactions and life circumstances, as they may have intrapersonal and interpersonal functions (Izard, 2009) (*see* Infancy and Childhood: Emotional Development). For example, emotions motivate behavior and decision-making, help in understanding the motives of other people, facilitate attention-focusing and help to prioritize between different goals. Emotions are transient and show variability over short periods of time. They may differ as a result of being exposed to different situations. By contrast, emotional abilities reflect relatively enduring patterns of emotional functioning

that are relatively stable over time. Examples for emotional abilities are emotional intelligence, the tendency to feel positive and negative emotions and satisfaction with life, emotional complexity and the capacity to express emotional experiences.

As with other forms of midlife development, changes in emotional abilities are varied and multidirectional (Charles and Carstensen, 2010). Research with respect to positive and negative emotions suggest that the tendency to feel positive affect and enjoyment and to be satisfied with life are relatively stable in the middle years but then show a decline in late periods of midlife and old age. In contrast, the tendency to feel negative emotions appears to decrease steadily from early adulthood to older adulthood (Charles et al., 2001; Mroczek and Spiro, 2005). This positive emotional developmental pattern reflects the tendency of becoming more prone to positive emotions and less prone to negative emotions over time in order to optimize well-being. An additional aspect of positive development refers to the tendency of becoming able to handle and process more complex emotional information and being self-aware of emotional complexity. This aspect includes the ability to tolerate tension and negativity in order to maintain emotional differentiation and complexity. The dynamic integration theory states people are challenged to balance increases in emotional optimization and emotional complexity across the life span (Labouvie-Vief et al., 2010). The integration of both aspects reflects a dynamic balance. Evidence suggests that from early to middle adulthood, the capacity for integration increases and later decreases due to cognitive limitations or poor emotion regulation strategies (Labouvie-Vief et al., 2010).

Emotion regulation strategies are very important in middle adulthood, as this period is a challenging and complex period with manifold environmental and individual changes. Emotion regulation strategies may serve as protective factors and help to adapt to life circumstances and stressful events, including multiple roles and responsibilities, developmental deadlines (e.g., biological clock), and other challenges associated with midlife. Indeed, research has shown that the regulation of emotion is related to adaptive functioning among middle-aged adults (Charles and Carstensen, 2010).

Motivational Changes

Motivations may also change across the middle years. The realization of long-term developmental goals such as having children depends on the opportunities that are shaped by the life span (Heckhausen et al., 2010) (*see* Motivation and Actions, Psychology of). The opportunities to realize developmental goals and tasks are age-graded and thus have developmental deadlines, as a result of biological (e.g., loss of fertility) and social constraints (e.g., social expectations about when certain activities and goals should be undertaken). For example, a middle-aged woman after the menopause is not able to get pregnant due to the loss of fertility.

To develop in an adaptive way, people have to balance between primary control processes that are directed at changing the world to bring the environment into line with one's needs and desires and secondary control processes that are directed at changing the self to bring oneself into line with environmental forces (Heckhausen et al., 2010). Primary control helps to pursuit goals, whereas secondary control supports goal flexibility and helps to cope with failure and challenges. These control processes show distinct patterns in middle adulthood. Secondary control processes tend to increase from early periods of the life span to the middle years and beyond. The capacity for primary control still increases in the early period of midlife, reaches the maximum in the middle period and finally starts to decline in the late period. However, according to Heckhausen et al. (2010) people constantly try to maximize overall primary control across the entire life span.

Motivational changes may also result from people's general tendency to perceive their time in life as either open-ended or as limited. The socioemotional selectivity theory suggests that the subjective perception of time has important implications for the selection of goals, activities, and preferences (Carstensen et al., 1999). When future time is perceived as open-ended, as is typical in young adulthood, people are strongly motivated to optimize their future by pursuing information and knowledge-related social goals. When people view their future as limited, as is typical in later life or when people are confronted with serious illnesses, emotional goals, meaningful social activities, and experiences become increasingly important (Carstensen et al., 1999; Charles and Carstensen, 2010). In the middle years, people begin to realize that maybe more time has gone by than remains. The realization of decreases of possibilities to pursue long-term goals in the future may be associated with giving up some developmental goals and dreams in midlife.

Personality Development

Human personality or the self may be viewed at least from three different perspectives including narrative, motivational, and dispositional perspectives (McAdams and Olson, 2010). The narrative perspective corresponds to internalized life stories. Life stories are the narrative understanding of the self to make meaning out of life. In addition, the motivational perspective refers to personal goals, motives, plans, values, hopes, and fears that are contextualized in time, place, and social role. Eventually, the dispositional perspective corresponds to personality traits that are relatively enduring patterns of behavior, thought, and feeling that are fairly consistent across a wide variety of situations and contexts. Individual differences in dispositional patterns are typically organized along the Big Five framework (John et al., 2008) and can be assessed from different perspectives (e.g., self-, other-, partner-, and metaperceptions of personality; Schaffhuser et al., 2014). Neuroticism, or low-emotional stability, contrasts even-temperedness with experience of anxiety, worry, anger, and depression. Extraversion refers to individual differences in the propensity to be sociable, active, assertive, and to experience positive affect. Openness to experience refers to individual differences in the proneness to be original, complex, creative, and open to new ideas. Agreeableness refers to traits that reflect individual differences in the propensity to be altruistic, trusting, modest, and warm. Finally, conscientiousness reflects the propensity to be self-controlled, task- and goal-directed, planful, and rule following. These individual differences are important because they predict life outcomes that are essential

in midlife, such as marital success, occupational attainment, and health (Roberts et al., 2007).

The most consistent evidence regarding changes in personality traits across adulthood is that people become more dominant, agreeable, conscientious, and emotionally stable across the adult years, or at least up through late-middle age (Allemand and Lehmann, 2012; Roberts et al., 2006). This pattern of change across middle adulthood is particularly important with respect to the primary social contexts of middle-aged adults (i.e., family, relationships, work, and community). For example, individual differences in the propensity to be self-controlled, task- and goal-directed, planful, and rule following are particularly important to be productive at work and thus to contribute to society. Similarly, individual differences in the tendency to forgive others are relevant in social settings including interpersonal conflicts and transgressions (Steiner et al., 2012).

The pattern of personality change reflects a trend toward greater maturity across adulthood in the sense of becoming emotionally more predictable and more attuned to social demands with age (Roberts and Wood, 2006). This pattern describes a socially effective personality that contributes to everyday life running smoothly and maintaining or increasing subjective well-being and life success. As dispositional traits show trends toward greater maturity in midlife, goals and narratives show an increasing concern with commitments to family, social relationships, civic involvement, and productive activities aimed at promoting the next generation (McAdams and Olson, 2010). Motivational and narrative aspects of the self tend to be more malleable than personality traits and are influenced more strongly by experiences in middle adulthood, making the person resilient or vulnerable to stress (McAdams and Olson, 2010).

Similar to changes in the cognitive, emotional and motivational functioning, personality change is characterized by many individual differences across the adult years (Roberts and Mroczek, 2008). This suggests variability in the degree and direction of personality change and may reflect the plurality and diversity of life experiences people can encounter in middle adulthood. Specific life circumstances and events may lead to different personality trajectories for different people (and vice versa: different personality patterns might lead to patterns of how to encounter, respond to and interpret situations), which can help to explain the substantial variability in midlife development.

Conclusions and Future Directions

Development in middle adulthood is an important issue. Four take home messages stand out. First, middle adulthood is a unique and relatively long developmental period with the primary functions of maintenance and adaptation to diverse midlife contexts and experiences. More theoretical and empirical work is needed to understand the nature and course of development from early to late periods of midlife. Second, middle adulthood is characterized by a wide variability in its nature and course. Therefore, more research is needed to understand why some people remain the same as they pass through the middle years of adulthood, while other people change, and also why people differ in the direction and degree of change. Third, middle adulthood is characterized by manifold changes in the environment and in the individual. More theoretical and empirical work is needed to understand the associations between changes in the environment and individual. Under certain conditions, environmental changes may promote or inhibit changes in cognitive, emotional, and motivational functioning and personality in midlife. Conversely, individual characteristics and experiences may shape the environment. Environmental and individual factors and their interactions may be responsible for change and stability through the middle years by means of dynamic maintenance and adaptation processes to life circumstances, stressful life events, developmental goals and tasks, and other influences. Similarly, research is needed to understand changes between diverse domains of individual functioning, such as cognition and personality. Fourth, as middle adulthood is a 'sandwich' period between other developmental periods with different experiences, it is important to examine the antecedents and consequences of midlife development. Research is needed to identify factors in earlier life periods that predict individual differences in midlife psychological functioning. In addition, midlife development may influence aging processes in old age. As such, research is needed to identify early warning signs of maladaptive processes for prevention efforts. Likewise, applied research is needed to develop interventions for middle-aged adults that promote healthy aging. To conclude, recent theoretical advances and empirical work suggest that the future is bright for the scientific study of development in middle adulthood including antecedents and consequences of midlife development.

Migrants and Migration in Europe

David Coleman, University of Oxford, Oxford, UK

Abstract

Since the 1950s, annual immigration to Europe has increased to almost two million persons. Migration dominates demographic change in many countries, making them ethnically diverse. It has important economic and social consequences; immigrants comprise about 10% of the workforce. The European Union has acquired powers over immigration policy, but policies of different countries vary greatly, many are restrictive; popular opposition to large-scale immigration is strong. The economic effects of immigration are controversial and conflicting, beneficial for immigrants, employers and some consumers, not for the domestic poor. Fiscal benefits are small, but there is strong competition for high-skill immigrants.

Background

Until the mid-twentieth century, Europe had been a continent of emigration. Between 1815 and 1914, about 54 million Europeans are estimated to have emigrated (Baines, 1991). But the twentieth century brought to western Europe migratory movements unprecedented for a millennium. First from the forced migration and ethnic displacements occasioned by the two world wars and their political consequences, the echoes of which continue today. Then, guest-worker programs from the 1950s and less formal labor inflows, brought migrants to Europe – to notably Germany – from poorer European countries and from outside Europe, from Turkey and from former colonial territories. In France, the UK and other countries, the citizens of colonies and former colonies also enjoyed for a while unrestricted rights of entry that had been acquired during imperial times. Many of the migrants expected to return home. Most did not, even when economic growth faltered. Instead, later family reunion and family formation made settlement permanent and growing through chain migration. Further inflow was attracted by postwar economic growth and facilitated by three peaceful postwar revolutions; in transport, communication and in human rights. Asylum seeking greatly increased after the 1980s. Until 1989, movement across the Iron Curtain into and out of eastern Europe was minimal except initially from East Germany. After 1961, the East German fortified border, including the Berlin Wall, reduced to a trickle the hemorrhage of population to West Germany.

Initially, the free movement of labor between countries of the European Union (EU) made relatively modest contributions to migration flows. All that changed after 1989 when the populations of the much poorer countries of eastern Europe were free to leave after 1989, especially after they were admitted to the EU in 2004 (8 countries: Czech Republic, Estonia, Hungary, Latvia, Lithuania, Poland, Slovakia, and Slovenia (the 'A8')) and subsequently (3 countries: Bulgaria, Croatia, and Romania) (Eurostat, 2008). Cyprus and Malta (the 'A2') also joined in 2004. Labor migration remains important, but most immigration to Europe in recent decades has not been (ostensibly) for purposes of work; the majority being spouses, dependents, students, asylum seekers, and illegal immigrants (Garson and Salt, 2011). Through all the processes above, especially chain migration, western Europe has become a region of mass immigration, almost irrespective of the aims of national immigration policies. As a consequence, substantial non-European populations have come to Europe for the first time, introducing new ethnic and religious diversity and raising important problems of integration.

Recent Migration Trends in Europe

Before discussing numbers, it is important to keep in mind that migration data are problematic and inadequate, although improving (e.g., US Bureau of the Census, 2005; Raymer and Abel, 2008). Harmonization even of migration data between EU countries has not been easy (Poulain et al., 2006). Estimates of net annual inflow in many European countries are not based on counts in or out, but rather on comparisons of registrations from a year to the next. The UK bases estimates of annual inflow and outflow from a small sample of voluntary interviews with international travelers. Persons recorded as permanent immigrants in a year have often entered in earlier years. There may be about half a million illegal immigrants to Europe every year. Data on the 'stock' of residents, according to citizenship and birthplace, have greatly improved, however (Lemaitre, 2005).

Immigration to the EU countries (In addition to the countries listed earlier, EU member states comprise Austria, Belgium, Denmark, Finland, France, Germany, Greece, Italy, Irish Republic, Luxemburg, The Netherlands, Portugal, Spain, Sweden, The United Kingdom (the 'EU15')) has generally risen in recent decades. Overall, the net inflow has often been higher than the gross inflow to the United States (**Figure 1**), although those figures are based upon different criteria. In 2011, 1.7 million people were estimated to have migrated to the EU from a country outside the EU27, and 1.3 million people already living in the EU27 migrated to another member state. Altogether, over 3 million people immigrated to one of the EU27 member states, while 2.3 million left (both figures include movement between EU states; Eurostat, 2013a). Most immigrants from outside the EU come from countries ranked as of 'Medium Human Development Index' (HDI) status, e.g., Morocco, China, Ghana, India, Ukraine, while 6% came from low HDI countries, e.g., Iraq, Pakistan, Nigeria, and most African countries. 35% came from high HDI (non-EU)

countries (e.g., US, Japan) and 4 and 3%, respectively, from European free-trade area (EFTA) (Iceland, Liechtenstein, Norway, and Switzerland) and EU candidate (Iceland, the former Yugoslav Republic of Macedonia, Montenegro, Serbia, and Turkey) countries. Most immigrants to EU countries still come from outside Europe, although the opening of eastern Europe has changed the balance since the 1990s. There was a very large increase, recently moderated, of migration from eastern Europe accession countries to the EU, especially to those few countries that did not initially impose restrictions on labor movement (UK, Sweden, Ireland).

From 2008, most states declined migration to EU in response to the economic crisis. Partly because of that, the recent European immigration scene is one of relatively incoherent and contrary trends in different countries. We are only slowly and with uncertainty recovering from that crisis. The problems of Eurozone countries have depressed immigration, while emigration from them has increased – mostly to Germany. That turnaround has reversed Germany's population decline. In 2012, net immigration of 369 000 to Germany more than compensated for the excess of deaths over births (−196 000), increasing the population by 173 000 or 0.2%, the biggest increase since 1995.

Restrictions on A8 labor movement were lifted in 2011 (although many had already entered irregularly). Restrictions on Romania and Bulgaria, more recent EU members, must be lifted in 2014. The consequences are awaited with interest, although many have already entered illegally. The more prosperous Central and European countries (e.g., Czech Republic) have modest net inflows of population. But most have lost population by migration since 2004 or earlier (e.g., Poland, peaking at −36 000 in 2006, down to −7000 in 2012). In the poorest countries, e.g., Bulgaria, the peak estimated outflow was −214 000 in 2001, −3000 in 2012; and in Romania, peak outflow was −458 000 in 2006, down to −3000 in 2012. However accurate or otherwise these figures are, outflow has undoubtedly been large and (until 2014) mostly short term or illegal. In the last-named countries, emigration has led to severe rural depopulation and accelerating population decline, a decline reinforced by chronic low fertility and high mortality. The former Soviet Baltic states (Estonia, Latvia, and Lithuania) have also experienced high outflows, especially the latter two, all the more alarming to them as their population size is so small. The Russian Federation, however, has recorded high net inflows, increasing from 99 000 in 2004 to 329 000 in 2012. It is the center of a different migration system, initially receiving many persons of Russian 'nationality' who suddenly found themselves to be 'foreigners' when the Soviet Union collapsed in 1991, later receiving inflows from citizens of the neighboring countries of the former Soviet Union (the 'near abroad'): Ukraine in Europe, and Uzbekistan, Kyrgyzstan, Kazakhstan, and other states in Central Asia and the Caucasus. That immigration, attracted by employment and relative prosperity founded on oil and gas, has helped to arrest and even slightly reverse the population decline in Russia that began after 1991.

The overall tendency for migration to increase (until recently) masks a number of strongly divergent trends (Figure 2). The UK showed a marked increase to become the largest recipient of immigration in the EU, displacing Germany between 2003 and 2010 from its previous top position. In 1993, net immigration to the UK had been negative. By contrast, Germany (until 2009) and France have experienced smaller and generally diminishing net flows, that to Germany being briefly negative, as was that to the Netherlands from 2003–07. Annual flows in each direction can remain very large even if the net balance is small. Flows are small in absolute numbers to small countries, e.g., Denmark, Norway, and Switzerland, are often large in relation to their national populations.

Figure 2 Net migration, selected European countries, 1997–2012. Source: Eurostat.

Spain and Italy, traditional emigration countries until the 1980s, had relatively modest published immigration figures until the late-1990s. Later migration, some of it illegal or unrecorded, from Latin America, North Africa, and eastern Europe, changed all that. When repeated amnesties regularized much of the illegally resident population, the picture changed radically (Figure 3). After 2007, net inflows fell precipitately, with many of the earlier immigrants, along with citizens, moving on to other EU countries (Figure 3). More people left Spain than entered it in 2011 and 2012. Migration to Ireland, 12 per 1000 population up to 2007 – a very high figure for a country accustomed to losing emigrants – became negative but has now increased again.

Migration Flows According to Purpose of Journey

It is difficult to make Europe-wide comparisons of the relative strength of inflows for different purposes, except asylum. However, in general, since the 1970s most (regular) migration has not been specifically for purposes of work but more for family reunion, family formation, as other dependents, study

Figure 3 Net migration, Spain and Italy, 1997–2012. Source: Eurostat.

and asylum seeking. In most of the guest-worker countries, of which Germany was the most important, labor migration was severely restricted following the oil shock of 1973. By that time, the traditional industries for which the mostly low-skill labor had been recruited were in any case either in terminal decline or were remaining profitable by replacing routine labor with automated processes. Although demand continues – and is likely to increase as populations age – for low-skill migration for services, for example, for the care of the elderly, cleaning, and catering, recruitment has increasingly concentrates on skills and competition has developed for highly skilled immigrants (Salt et al., 2004; Lowell, 2005), with selective programs to attract them (documented in McLaughlan and Salt, 2002) including the EU Blue Card program. High-skill migration is often mediated through intracompany transfers.

The spouses, dependents, students, asylum seekers, and the rest may work and do, of course, but their labor force participation can be low, a handicap that can extend into the second generation (OECD, 2007: pp. 62–95). Students may stay to work, and in some countries graduates are now encouraged to do so. In 2001, the proportion of non-EU immigrants to Sweden entering as labor migrants was 3% (gross inflow) and to Denmark in 2005 2% (net inflow). By contrast, in some years labor migration to Germany has been substantial; 380 000 entered for work in 2004 out of a total gross inflow of 602 000 foreign citizens (63%, OECD, 2006).

Family migrants and dependents, mostly from outside Europe, are more likely to remain than are skilled labor migrants, more of whom come from the developed world (Rendall and Ball, 2004). The self-perpetuating process of chain migration from poor countries, creating substantial and growing transnational populations is described as 'cumulative causation' by Massey and Zenteno (1999). Most of that was neither inevitable nor planned. It followed on from a labor migration assumed to be temporary through the development, for humanitarian reasons, of systems of rights for family migration and other immigrant entitlements, in conjunction with the other postwar 'revolutions' of information and communication (Freeman, 1994; Martin et al., 2006: p. 222). The example of France from 1946 illustrates the transition from labor to family migration typical of many European countries (**Figure 4**).

The pattern of gross inflow to France in 2010 is shown in more detail in **Table 1** below, excluding immigration from the European Economic Area (EEA). 95% of that inflow was from outside Europe, 54% was from Africa, 25% was from Asia. Immigration from developing countries is mostly of family, spouses, dependents, students, and asylum. Only 9% of non-EEA migrants entered for work. 45% entered for family reasons (reunification and new marriages), 31% were students. These data do not show the number of persons from other EEA countries entering for work. In 2005, EEA immigration to France comprised 21% of the total, 34% for work, 6% family, and 46% retired and other. While patterns vary, these are not untypical of inflows to western European countries.

Until about 2004 flows within the EU were not great and were relatively numerically balanced. The removal of internal barriers to movement had not ironed out persistent regional disparities in labor shortage and surplus, and the earlier EU member states were relatively similar in economic level (Rees and Kupiszewski, 1999). Long-standing cultural differences even between the different regions of European countries in the western part of Europe still strongly affect internal migration patterns, for example in Germany (Falck et al., 2010). With an

enlarged EU, the inflow of people from eastern Europe to the UK, Ireland, and Sweden following the accession of Central and eastern European counties to the EU in 2004 (A8 countries) changed that. A cumulative total of 1.1 million applications under the Workers' Registration Scheme had been made to the UK between 2004 and the end of the scheme in 2010 (gross inflow). The UK government, which chose not to adopt the 7-year delay on free movement of labor after A8 accession, which was imposed by the other major EU economies, had forecast 13 000 per year. The Polish population in the UK has increased tenfold since 2004, to over 600 000, and births to Polish-born mothers are now the single largest national category of births to foreign-born women in England and Wales.

However, even before the economic crisis, migration from the A8 countries was slowing and the return migration increasing. As economies of east European source countries grew, stimulated by EU membership, the value of Eastern currencies rose, and so diminished the exchange-rate advantage of working in the west. Furthermore, rapid domestic growth together with labor shortages exacerbated by the emigration has promoted domestic labor demand and wage-rates. Despite all that, eastern European migration to western Europe remains substantial, augmented by inflows from Bulgaria and Romania, including numerous Roma/gypsies.

Emigration of citizens from some western European countries increased, including the UK (Evans et al., 2007) and Germany (Sauer and Ette, 2007), and even France. In the Netherlands, the outflow was attributed to dissatisfaction with domestic conditions, crowding, and social and environmental deterioration (van Dalen and Henkens, 2007).

Asylum Seeking

In the Cold War period, most asylum seekers came from behind the Iron Curtain. Inflows were small, uncontroversial, and often politically useful to Western countries. All that changed in the 1980s when asylum seeking from outside Europe began to accelerate, from Iran, Turkey, Sri Lanka, and elsewhere. It grew to very high levels in the 1990s, partly in response to political crises in the Balkans and Middle East. Germany was the favorite destination through its economic attractions and the generous provisions in its Basic Law. Claims to Germany peaked at 438 190 in 1992 before returning to lower levels (19 165 in 2007). Asylum claims fluctuate considerably depending on the political situation in sending and receiving countries, and economic trends, but there are always substantial streams from South Asia, the Maghreb, and Middle East and sub-Saharan Africa. Much of it is managed by traffickers who keep abreast of political developments and switch destinations accordingly. Asylum seeking to EEA countries has increased since 2008 from 257 475 applications to 373 995 in 2012. Applications to Germany (the most popular destination) almost tripled to 77 650, doubled to Sweden (to 43 945) and to Switzerland (to 28 640), and increased 50% to France (to 61 455). Applications to weaker Eurozone countries (e.g., Greece, Ireland, Italy) fell sharply. Most claims are judged to be unfounded (2/3 of first instance decisions by EU28 countries in Q2 2013) but most applicants will remain in Europe. The latest figures at the time of writing show an extraordinary increase in claims – 50% higher in Q2 2013 than Q2 2012 (Eurostat, 2013b). Claims to Germany doubled in that time. Asylum seeking seems to have discovered Central and eastern Europe, which formerly received few claims. Claims to Hungary increased 25 times since Q2 2012, to Bulgaria four times, to Poland three times. Russians and Kosovars comprised half the increase, after Malians and Syrians (Russia 16845, Syria 8310, Kosovo 8140, Afghanistan 6075, Pakistan 5965, Somalia 4285, in Q2 2013).

Foreign Citizens and Immigrants in the EU Countries

33.3 million foreign citizens have lived in the EU27 countries in 2011, 6.6% of the total population. They were strongly concentrated in western Europe. Of these 21 million were citizens of non-EU countries. Romania, Turkey, Morocco, and Poland were the four most important countries of foreign citizenship in the EU27 countries in 2011. Data of population of foreign origin based on citizenship substantially

underestimate the number of residents born abroad, through the high level of naturalization. In some countries, the number of naturalizations has been about equal, each year, to net immigration flows. Better data on birthplace now gives us a better estimate of the number of immigrants living in European countries. 48.9 million foreign-born residents lived in the EU27 countries in 2011, 9.7% of the total population. 32.4 million of them were born outside the EU and were therefore immigrants from outside Europe, a Figure 50% higher than the number according to citizenship (Eurostat, 2012, 2013b).

What Can Be Said about the Future of Migration?

Migration theory remains fragmentary and cannot easily forecast the likely future trends of aggregate migration flows. Many of the events driving it, notably the economic trends and even more so, political change, are unpredictable. Comprising numerous unrelated flows from many origins for unconnected purposes, migration has defied satisfactory modeling or projection except where it is dominated by regular labor migration. Political processes at home and abroad can be paramount. For population projection, most national statistics offices assume the continuation of the current level or the extrapolation of recent trends. Critics of such a simple approach are usually baffled to suggest anything better. However, increasingly sophisticated approaches are being made to improve understanding (Howe and Jackson, 2005; Eurostat, 2007; Lemaitre et al., 2007; Duque and Montoso, 2008; Raymer and Abel, 2008; Kim and Cohen, 2011). Economic models succeed best when migration is primarily for labor, usually it is not. The buoyant Norwegian economy provides an exception. The econometric model of Brunborg and Cappelen (2009) fits past trends well and, for example, predicts a downturn in immigration to Norway as its economic attractions are expected to fade as its oil runs out.

Generally, migration pressure to developed countries from the South is likely to remain high, and possibly increase for some time, before declining. Economic and demographic disparities between the global North and South continue and in some cases have widened. Whether moving specifically for work or for a 'better life' in general, residents of poor countries are usually materially better off somewhere else. On the demand side, employers demand easy access to labor, especially if earlier migrant flows have made them dependant upon it, and if population aging or labor market protection restricts domestic supply as in many parts of Europe. Many third-world countries remain politically unstable. The 'cumulative causation' of established immigrant populations provokes further immigration through networks and chain migration (Gurak and Caces, 1992; Mitchell and Pain, 2003; Massey and Zenteno, 1999). Commitment to human rights, family reunion and asylum conventions, and growing ethnic electorates make it difficult for western states with liberal pretensions to restrict immigration effectively (Freeman, 1994; Castles, 2007). In Europe, the EU Commission, supported by the UK government among others, has stated that it wishes to expand EU membership to countries on the edge of Europe and beyond: to Ukraine (population 50 million), to Turkey (population 76 million), and even to North Africa, countries with larger populations and even lower levels of development than those recently admitted. This would guarantee migration pressure well into the future (Rowthorn, 2009). Rising economic inequality within countries such as the UK may also encourage immigration (Hatton and Tani, 2005).

Most commentators have concluded that the economic downturn will have only transient effects on inflow, 'A8' apart, because most immigrants are not labor migrants. Marriage migration and the inflow of dependents, students, asylum seekers, and others may be little affected (Dobson et al., 2009; Beets and Willekens, 2009; OECD, 2009: pp. 63–65). Nonetheless, provisional data so far show that its effects have been substantial in some countries (Papademetriou et al., 2011).

Many skilled labor migrants come from India to developed countries, notably to work in the IT sector. Crisis apart, this and similar flows have been increasing (Salt, 2009). But in the long run, labor migration from India may well decline, if the continued rapid growth of the Indian economy absorbs more of its own specialists, That applies a fortiori to China, with its more rapid economic growth and faster population aging. Basing themselves on labor market considerations, Barrell et al., 2009, using the model of Mitchell and Pain (2003), project that the narrowing of the economic gap would reduce substantially net migration to the UK from the A8, the Old Commonwealth countries, India, Latin America, halving the current officially projected increase in migrant stock by 2030 (p. 37). But that scenario does not take much account of noneconomic migration.

Students are a major component of migration flows to Europe from the third world, and up to stay to work or marry. China dominates these flows, with 350 000 students studying abroad in 2007, projected to be 645 000 in 20 years. China has a huge program to improve its domestic higher education – numbers are growing at 25% per year between 1999 and 2004. But even that does not appear to compensate for the growing demand. Chinese students overseas are projected to increase to 645 000 by about 2025. Eventually, the growing domestic sector and the demographic diminution of the numbers of young people in China must reduce overseas migration, but that is unlikely to become apparent for decades. In the meantime, other countries are sending more students abroad: from India 130 000 in 2005, projected to increase to 300 000, followed by South Korea (127 000), Morocco (106 000), and Turkey (104 000) (Banks et al., 2007; Maslen, 2007).

Arranged marriage – preferably first-cousin or uncle-niece in Pakistani culture – is favored in many traditional societies and is a growing component of migration to many European countries, displacing old-style family reunion with new family formation (e.g., Charsley et al., 2012). Some of it motivated more by the prospect of migration than the pleasures of marriage. In the UK, marriage migration from the Indian subcontinent has been growing roughly *pro rata* with the growth of the young South Asian population in the UK. In the Netherlands, it had become the most important component of all migration from North Africa and Turkey. Marriage migration comes from many parts of the traditional world; for example, numbers from sub-Saharan Africa to the UK trebled from 1996 to 2006.

Otherwise, and medical personnel apart, immigrants from the least developed third world, are mostly asylum seekers, students, dependents, and illegal entrants. Chronic political instability, rapid population growth, and economic and environmental fragility are likely to keep inflows high for the foreseeable future. It may increase substantially if global climate change has early effects. The latter may override the outcomes of any scenario based only on socioeconomic and political considerations. Its widely forecast effects have now crept within the time horizon of population projections. If those forecasts prove to be correct, then there could be major implications for international migration.

Effects of Policy

In part, the volatile track of migration trends follows from unpredictable policy and political changes in sending and receiving counties (Hollifield, 2000). Some of the most important political changes in sending countries are those that provoke, or ease, asylum seeking, either as a result of persecution of specific minorities promoted by governments or not controlled by them (e.g., Kurds in Turkey, Christians in Palestine, Iraq, and Syria), or economic mismanagement, or both (e.g., Zimbabwe). The regime change in Iraq, which was hoped to reduce the flow of refugees from the previous regime, has instead provoked the flight of well over a million people to neighboring Syria, who now find that they have moved from the frying pan into the fire.

In the receiving countries, successive governments differ in their perception of migration (Schain, 2008). They receive contradictory messages from business demanding access to skilled and other labor, and worries about the care of an aging population, and the popular dislike of large-scale immigration, which is general in Europe (Martin, 2010). New policies on immigration can be brought in by governments elected for other reasons (for example, the Labor government in the UK 1997–2010, which liberalized policy). In other cases, immigration itself is a factor in the change of government, usually to control it further (for example, the UK coalition government elected in 2010). For well-known reasons, it is easier in liberal democracies to encourage immigration than to restrict it. For example, the incoming Labor government in the UK reversed the previous restrictive policy of the previous 30 years, promoting immigration for a variety of reasons including expansion of labor supply and GDP. By mid-2000s, this trebled net immigration compared with the early 1990s, taking net inflows to the highest level in the EU except for Spain and Italy. The radical increases in net inflows to those two countries arose partly because of political change, including the return of a Socialist government in Spain favorable to migration. Amnesties regularized large numbers of illegal immigrants. Policy changes in Sweden and Denmark to favor skilled labor migration have also increased overall net flows to those countries, and in Sweden immigration is projected to increase to mid-century (Statistics Sweden, 2009). For most of the postwar period, Germany received about two-thirds of immigrants to Europe and two-thirds of asylum seekers. But a variety of measures, beginning with a reform of the Fundamental Law in 1991 to limit asylum seeking, and later to regulate the inflow of *aussiedler* (people of German origin in eastern Europe), together with less impressive economic growth, greatly reduced net immigration from 1990 to 2009 (**Figure 5**).

In France, labor migration had been selective and restricted for some time (**Figure 3**). A succession of measures: imposing tighter conditions on asylum, naturalization, marriage migration, and measures against illegal immigration and to facilitate deportation have developed over the decade, especially under the Presidency of M. Sarkozy (2007–12) alongside a new policy on 'national identity.' A different approach

Figure 5 Net migration to Germany, 1954–2012, according to citizenship. Source: Statistisches Bundesamt, Wiesbaden. Up to 1990 German Federal Republic only.

to migration is adopted by the new Socialist government of M. Hollande.

Some policies aim to restrict some immigration streams (notably those not focused on economic contributions), while leaving or even promoting others. Thus in Denmark, legislation, since 2002, has severely tightened the requirements for marriage migration, reducing the flow to one-third of their previous level by 2005 (Rockwool Foundation Research Unit, 2009). As of 2013, these are the latest data available from Statistics Denmark (**Figure 6**).

Danish policy has also been to admit more skilled workers, so the total volume of immigration is now higher that 10 years ago, although its composition is considerably different. Marriage migration (especially in respect of the second generation) among Moroccans and Turks in the Netherlands fell sharply following a policy change in 2004 (Statistics Netherlands, 2009). As a consequence, a higher proportion of Turks residing in the Netherlands are now marrying spouses of Turkish background who are also living in the Netherlands, rather than spouses introduced from abroad.

Despite all this, the power of European countries – especially those within the EU – to limit immigration is limited. Most immigration is not (ostensibly) for work. All the countries concerned are signatories to treaties and conventions (the Geneva Convention on Refugees, the European Convention on Human Rights, and EU legislation), which give considerable entitlements to persons wishing to enter the EU for purposes of marriage, as dependents, and for asylum, and which restrict powers of deportation. While individual counties may seek to restrict the conditions for such entitlements, judgments of the European Court of Human Rights constantly expand them. National freedom of action in these areas is considerably restricted in the EU.

Economic Consequences of Immigration

Much orthodox opinion, supported by neoclassical economic theory and the concerns of business and employers, holds that immigration benefits economic growth, increasing GDP, expanding the workforce, bringing skills, damping wage inflation, compensating for population aging, and a diminishing workforce in very low-fertility countries. Critics of the economic and social effects of large-scale immigration risk being labeled as misinformed, irrational if not racist, or 'xenophobic.' That became the establishment view (Coleman, 2003), although electoral reversals have forced a retreat from this moral high ground. Public opinion has been usually at variance with elite views on immigration (Chamie, 2009), usually favoring restriction, not expansion. In Europe countries, unlike countries of European origin overseas, immigration has no place in perceptions of national identity, but is normally seen as a challenge to it (Collier, 2013). Doubts have been raised about the unqualified economic benefits of immigration, suggesting that immigration may impose net costs, not benefits, on receiving society even by the narrow standards of fiscal accounting (Wadensjö, 1999; Borjas, 2003). This is very difficult to evaluate. Most studies conclude that the fiscal benefits overall are small; beneficial in respect of skilled migrants mostly from richer countries, not so from less skilled migrants mostly from poorer countries. The first large-scale international comparative study of fiscal effects concluded that over the OECD member countries, 'the fiscal impact of immigration is close to zero on average' (OECD, 2013: p. 9, and 125–161). As to economic growth, naturally immigration increases GDP as it increases population, assuming that most immigrants work. But it has little effect upon GDP per head, which is the appropriate measure of welfare (House of Lords, 2008). Benefits are very uneven. The unequivocal beneficiary of immigration is the immigrant. Employers benefit from easier access both to skilled and to unskilled labor, as do consumers of services. There is stiff international competition for talent in a global market. Universities gain highly talented staff and researchers, and student applicants, especially from the developing world. The poorer part of the domestic population does much less well, exposed to competition and to downward pressure on wages. Evidence is conflicting on the effects upon unemployment. But immigration can flourish, while domestic

unemployment is high (as in Spain; OECD, 2013: p.19) and high proportions of the working-age population – especially youth – remain economically inactive. This seems perverse.

All developed countries have aging populations, but the rapid population aging and incipient or actual population decline in some low-fertility counties of southern, central, and eastern countries has promoted claims that immigration is needed to maintain population and workforce and to ameliorate population aging. Earlier delusions that immigration could 'solve' population aging, promoted by a misinterpreted UN report (2000) have now mostly been exploded (Bijak et al., 2008). As in most policy areas, political considerations will overcome supposedly scientific research-based prescriptions, and immigration policy can change abruptly as a result of the fall of the electoral dice.

Effects on Population

The effects on the population of European countries are substantial, but diverse (Coleman, 2008; Rowthorn, 2009). As might be imagined, the prosperous countries of western Europe (in the broad sense) have been attractive to immigrants, including to immigrants from the former communist countries of Central and eastern Europe. The latter for the most part have lost population by emigration to the west, although in some cases that is compensated or more than compensated by new migration from the west (e.g., to the Czech Republic) and from further east (Ukraine) and the global South; in transit to western Europe, but in many cases remaining.

The Russian Federation is an exception. After the fall of communism it became a major country of immigration, initially of Russian nationals departing newly independent former Soviet states (the 'near abroad'), more recently a larger number of the nationals of those states. Net immigration in 2006 was 132 319. By 2009 immigration, estimated at 240 000, was reported to have just balanced the natural decrease of the population, generating a small increase in population for the first time since the mid-1990s. Immigration increased to 329 000 in 2012.

In western Europe, a number of countries with moderately high fertility still have positive natural increase, thanks to demographic momentum, assisted by the higher birth rates seen almost everywhere in recent years (some Scandinavian countries, France, the UK). With current migration, their populations are projected to increase by up to 20% by mid-century. Others (Spain, Italy) would decline substantially without their current high immigration, and the population of Germany fell from 2004 to 2011 until growth was restored – at least for a while – by the new high immigration depicted in Figure 3.

Formerly relatively modest in comparison with the number of births and with natural increase, and sometimes negative, net immigration now exceeds natural increase in most European counties and even approaches (Switzerland and Norway in 2011) the total number of live births each year (Table 2). If these trends continue, populations of immigrant origin will reach high proportions of the national population in a few decades, possibly eventually becoming the majority (Figure 7).

Projections of future population by national origin have been made for several European countries up to mid-century or 2060 (Coleman, 2006). In most cases, they are based on the assumption that immigration will continue at approximately recent levels and that fertility differentials will diminish or disappear. On those assumptions, populations of 'foreign origin' or 'foreign background' (mostly defined through population registers as first and second generation together) would rise to between 15 and 35% of the populations of some European countries by mid-century. Of those, about one-third is projected to be people of other European origins, two-thirds from outside Europe (Figure 8).

Table 2 Selected Western countries, Comparison of live births, net immigration, and natural increase 2011

	Population 1 January 2011	*Live births*	*Natural increase*	*Net migration*	*Net migration as percent of births*

Pan-European Policy Development

The European Commission (2005, 2008), had gradually extended its control over immigration policy in EU countries. The Schengen common borders area has been established including most EU member states (not UK). A 'Blue Card,' inspired by the US' Green Card system, to encourage highly skilled labor migration was formally adopted in the EU as a directive in 2009. The criteria are demanding and the take-up has been slight. The demographic and labor market and economic scenes in European counties seem too diverse for any single immigration policy to be appropriate. Common asylum policy is an exception. A Common European Asylum System was begun in 1999 at the EU summit in Tampere and successively consolidated, most recently in June 2013 for implementation in 2015 (European Commission, 2013).

Concluding Remarks

To recap, immigration is the dominant demographic driver in many European countries, provides a growing proportion of

Figure 8 Projected growth of population of immigrant or foreign origin 2000–50, selected countries, as percent of total population.

the workforce, and is changing the composition of the population in an increasingly visible fashion. Trends and policies remain diverse, but most indications are that immigration will continue at a high level. Many of the streams to the EU (family, dependents, Asylum) are driven by entitlement and are difficult to moderate.

In some of the countries mentioned above, the labor force is not projected to decline for some time if at all and labor migration is concentrated upon filling highly skilled shortages. Elsewhere, very low birth rates, if continued, may to provoke such future labor shortages, which only immigration can resolve even if fertility does recover. But in some continental countries, many of the labor shortages of which employers, governments, and analysts complain follow from restrictive labor market policies that favor those in employment, not those seeking it, overgenerous retirement and welfare arrangements and high payroll taxes. This 'European social model,' notably in southern Europe, contributes to high unemployment, especially of youth, low workforce participation rates, and dependency on immigrant labor, often irregular, to provide flexibility. Reforming all of this has been slow, painful, and difficult, although spurred recently by economic crisis. These are the same populations, with their 'familist' culture, that also suffer the lowest birth rates and consequently the most rapid population aging (Dalla Zuanna and Michielin, 2003).

So in the near future, at least, there are several reasons for supposing that substantial reductions in numbers of international migrants are unlikely. Global population will rise, especially in Africa and poorer Asian countries, increasing emigration pressures. Environmental deterioration will encourage emigration from marginal areas, partly arising from population pressure on land itself, partly from the effects of global climate change. The magnitude and form of the latter, and its effects upon population, are doubly uncertain. If the economy continues to be globalized, new migration sources may emerge. The aging of populations in OECD countries, especially those with chronic low birth rates, will strengthen arguments for labor immigration, particularly if cultural and political obstacles persist to the rationalization of labor market and retirement arrangements in those countries. Competition for skilled and well qualified migrants will continue. Insofar as immigrants are naturalized and can vote, growing populations of immigrant origin may make it more difficult for political parties opposed to large-scale immigration to win office. Set against that, popular opposition to such migration has been growing in a number of European countries and has provoked a number of electoral surprises. And in the much longer run, as the economies of sending counties develop and their populations age, the assumption of unlimited labor supply through immigration may prove to be false.

Abstract

This article reviews the thinking on migration and development from two points of view. First, it looks at more conceptual ideas in the academic literature on long-term and macrolevel approaches to the topic. Second, it examines approaches to the management of migration in the current policy debate on migration and development. The focus is primarily on international migration, although reference is made to internal migration where appropriate and opposing views and critical approaches are highlighted. The article conceptualizes migration as an integral part of development that changes systematically as development, however defined, evolves.

Introduction

Migration is both a consequence and a cause of development and is an integral part of the development process. Analyses of migration generally involve the study of the factors that bring about the population movement, the so-called drivers of migration. Analyses also incorporate the impact that the movement has on both origin and destination areas. Both the drivers and the impacts can be seen as aspects of development.

Migration includes both movements within a country's borders, internal migration, and movements from one country or territory to another, international migration. Simple in concept, migration has proven extremely difficult to measure in practice in a way that can give comparative data from one part of the world to another. Just one difficulty is that migration, international as well as internal, is rarely a simple, one-way 'permanent' move from one jurisdiction to another, but rather a complex path of return and remigration. If forms of temporary migration are to be incorporated into the discussion, how are they to be defined? Development, too, is an equally complex term, its meaning often assumed without precise definition. Both migration and development are multidimensional terms.

Migration and development in this article will be considered from two perspectives: first, migration as an integral part of development and how forms of migration change with development and, second, the perspective of the current debate on migration and development in which migration is seen to be something that can be promoted to bring about development. The primary focus in this article will be on international migration but readers should be aware that many of the points made apply equally to internal migration.

Migration as an Integral Part of Development

At the simplest level, migration in a premodern agrarian society was very different from that associated with a modern, highly urbanized society today; not that the former was static (it was not) and the latter highly mobile, but the means, speed, volume, and composition of the flows of migration in the two societies are very different. Available technology determines how fast and frequently people move. Hence, if technology is how we measure development, the relationship is fairly clear. In the year 1774, some 265 ships carried 5027 migrants from English and Scottish ports to the Americas, an average of 19 emigrants per ship (Bailyn, 1987: p. 101). Almost exactly a century later, in 1873, 17 companies were operating 173 steamships between Europe and New York (Nugent, 1992: pp. 31–32), many carrying more than a 1000 passengers each. Over a century later again, in 2007, there were some 425 000 flights across the Atlantic, and International Air Transport Association (IATA) forecasts are for 3.6 billion passengers worldwide in 2016, up from the 2.8 billion in 2011 (IATA, 2012). Clearly, most people who fly today are not migrants setting out on a new life but short-term travellers on business or vacation. Nevertheless, these travellers are both producers and consumers of a global economy that can only exist through our ability to move further, faster, more frequently, and more safely than ever before. Development, in its broadest sense, has been associated with increased movements of people and the emergence of different forms of population movement, which complicate any simple approach to migration and development.

United Nations estimates placed the number of international migrants in the world at 232 million in 2013, around 3% of the population (United Nations, 2013). While the absolute numbers of migrants had increased from 154 million in 1990 and 175 million in 2000, the proportion of the world's population that was defined as migrant under United Nations definitions had remained around the 3% mark. One can argue that the increased numbers of people migrating and moving are simply the result of an increase in global population numbers from 5.3 billion in 1990 to 7 billion in 2012.

Although the number of migrants in the world is a function of the size of the population, the resultant numbers of movers are not a simple outcome of that expansion. Nevertheless, this introduces into the equation those aspects of development in agriculture, industry, public health, housing, medicine, and transport that have contributed to the decline in mortality, the modern rise in population numbers, and the subsequent decline in fertility. How all these variables, and more, interact to generate migration and development outcomes creates a complexity that is captured in the idea of a 'nexus' as in 'the

migration-development nexus' in which all things are connected (Faist et al., 2011; Nyberg-Sørensen et al., 2002; Mossin Brønden, 2012; Phillips, 2011). Migration and development, however defined, are two processes that vary across space and through time, and it seems relevant to commence the discussion with approaches that attempt to conceptualize the complexity from this point of view.

Mobility Transitions

The geographer Wilbur Zelinsky was the first person to attempt to link migration with the changing patterns of mortality and fertility that can be described in the model of the demographic transition in his article on the 'hypothesis of the mobility transition' (1971). He expressed this most succinctly as follows:

> There are definite patterned regularities in the growth of personal mobility through space-time during recent history, and these regularities comprise an essential component of the modernization process.
> (Zelinsky, 1971: pp. 221–222)

If we substitute 'development' for 'modernization,' which was a term of its age, we have a very clear statement of how migration is integrated into development. Certainly, Zelinsky's hypothesis was not the first time that migration and development had been linked. From the time of Ravenstein in the late nineteenth century, economic factors have been seen as among the major 'drivers' of migration but Zelinsky's contribution was to show how migration changed over time and in sequence with changes in mortality and fertility, and to bring migration into the demographic transition.

Zelinsky identified five types of migration: international; frontierward; rural–urban; urban–urban and intraurban; and circulation and showed how their importance changed through the five stages of the demographic transition from high fertility and mortality to low fertility and mortality. Zelinsky never attempted to show how the changes in the various types of migration were linked to specific dimensions of development such as business cycles, global shifts in industrial production or transportation systems, let alone changes in political development. The links with technology perhaps became most explicit in the final two panels of **Figure 1**(f) and 1(g). In panel (f), he envisaged potential migration being absorbed by forms of circulation as commuter transportation systems permitted people to circulate over longer distances rather than having to migrate more definitively to find a job. Perhaps more speculatively, he also hypothesized that the development of telecommunication systems, including video conferencing, might suppress circulation and, presumably, migration, in a super-advanced society.

The hypothesis of the mobility transition was a grand theory, macrolevel model as populations respond to development. Although based on the historical experience of the Americas, it had undoubtedly broader relevance and for the first time attempted to integrate the three demographic variables as they responded to development. The model has been modified, particularly where applied to specific cases in both developed and developing worlds (Skeldon, 1990) and in terms of global spatial diffusion (Skeldon, 1997). Although it is easy to be critical of its broad sweep and its unilinear nature, it was in many ways ahead of its time in envisaging the shifts in mobility consequent upon developments in technology. It is a true 'classic' in human geography (Woods et al., 1993). To bring a narrower focus to the academic debate on migration and development, the consequences of the flows for origin and destination need to be examined.

Of Destinations, Origins, and Flows

Migration clearly involves an origin and a destination and flows of population between them. The consequences of the migration for the development of origins and of destinations can be quite different. However, to conceptualize migration as a simple flow from an origin to a destination is deceptive as it obscures many return, circular, and onward movements. Attention must therefore focus on the nature of the linkages between origin and destinations, but first a brief consideration of each is necessary.

Destinations

Migrants are seen to be a loss to their area or country of origin and a gain for their country of destination in more than just numbers. Globally, destinations are highly concentrated and, in 2013, the top 10 countries of destination accounted for 51% of global migrants, with the United States hosting fully 20% of the migrants (United Nations, 2013). Only a few of these countries, including the United States, see migration as part of nation building, but all benefit from the addition of mostly young and often relatively well-educated migrants. It is generally considered that migrants are a gain and make a positive contribution to their destinations. Most are young adults and they generate more wealth through work and tax than they consume through welfare and services. The destination state has not paid for their education and many migrants return or retire to their origin countries relieving the destination state of the costs of their care in old age.

However, the dilemmas and contradictions of migration and development are also seen in destination areas. The arrival of migrants in the new worlds to Europeans in the Americas and Australasia marginalized indigenous inhabitants, and an assessment of development from their point of view would be very different from that of the immigrant groups. Significant immigration costs can be incurred in the integration of peoples from very different backgrounds, differences that can generate social and political tensions. A substantial literature has built up for destination areas on the processes of assimilation and integration in destinations, as well as on alternative strategies of multiculturalism, which bear only indirectly on the migration and development debate. Nevertheless, despite these costs and an increasing public and political opinion against migration in many developed economies, the contribution of migration to the development of destination areas is seen to be positive by those assessing the evidence. See, for example,

Figure 1 Zelinsky's schematic representation of the changing levels of various forms of mobility through the demographic transition. Source: Zelinsky, W., April 1971. The hypothesis of the mobility transition. Geographical Review, 61 (2), 233. © Elsevier.

Dustmann and Frattini (2013) for the United Kingdom for one recent assessment of the evidence.

Origins

It is the impact of the migration on the origin countries that is more contested and which has received most attention in the migration and development debate. Many consider the loss of migrants to be a brain drain that can prejudice a country's development. However, the analysis of the available evidence has produced a more nuanced picture. Even in the health sector, the data show that those countries with the poorest basic health measures in sub-Saharan Africa were also those with the least emigration of health workers. In addition, attempts to reduce or even stop the emigration of health professionals did not alleviate skill shortages in the countries concerned (Clemens, 2013; Skeldon, 2008). The argument is also made that the exodus of the skilled in particular fields from any country is more likely to encourage other young people to embark upon training in that particular skill, perhaps with a view to future migration. However, not all will want or be able to emigrate upon completing their studies and the country will build up a pool in these particular skill areas with the result being a brain gain (Commander et al., 2004; Mountford, 1997; Stark, 2004). However, the evidence for this eventuality is not conclusive (Lucas, 2005).

More broadly, it is argued that any loss of both skilled and less skilled migrants from a country is compensated by money

sent back as remittances, and it is remittances that lie at the heart of the migration and development debate. The reason is clear: the sheer size of global flow that is estimated to reach US$550 billion in 2013, of which $414 billion will flow to the developing world. It is estimated that this latter component will increase to $540 billion in 2016 (World Bank, 2013). Larger than global aid transfers and larger than even foreign direct investment in several countries, this source of funds is seen as a powerful force for poverty alleviation in particular and for development in general (**Table 1**).

The top recipient countries are China and India, which account for almost one third of the amount flowing to the developing world. Globally, in 2012, it was the middle-income countries that accounted for virtually 70% of the total, with flows to high-income countries accounting for a further 24%. Hence, only 6% of remittances are flowing to the poorest countries, though relatively small volumes can have a large impact. For example, remittances account for 48% of the GDP of Tajikistan, 31% of that of the Kyrgyz Republic, 25% of that of Lesotho and Nepal, and 24% of that of Moldova (World Bank, 2013).

The impact that remittances have will vary by the size of the country, as well as by the number of migrants and where they originate in the countries of origin. Migration is not a random event and areas of origin, like areas of destination, tend to be concentrated in certain parts of a country. Hence, remittances tend to flow back to particular areas, which may not be the poorest. Some 80% of households receiving remittances from international sources in Peru were found to be in the coastal regions of the country (57% in the capital Lima). Only 5% were in the rural sector that accounted for over one quarter of the total population (cited in Skeldon, 2011: p. 109). Remittances are likely to reinforce existing inequalities: the poorest of the poor rarely migrate internationally as they cannot afford to do so, and it seems unlikely that remittances reach the poorest people in the poorest parts of countries. Nevertheless, remittances resulting from internal migration and accounting for a greater number of migrants may reach more areas in the poorer parts of a country. However, these migrants and these remittances are so often excluded from the discussion of migration and development. One notable exception is Adams (2006) who showed that remittances from internal sources did have a slightly greater impact on poverty reduction in Guatemala than those from international migration.

A Transnational Turn in Migration and Development

The focus on flows of money and of skills draws attention to the nature of the linkages between origins and destinations and, most importantly, the forms of the migration. Much of the migration is not 'permanent' but involves return to, and circulation between, origin and destinations. Even the 'great migration' across the Atlantic in the second half of the nineteenth century involved significant return in which rates of 50% appear not to have been uncommon (Nugent, 1992). With the modern forms of transportation noted earlier, return on a longer- or shorter-term basis is much easier. However, it is not simply a return movement: it is the ability of migrants to participate in the ways of life in both origin and destination communities, a process that has come to be incorporated under the terms 'transnational communities' and 'transnationalism.'

Transnationalism is part of the whole process of globalization in which large parts of the world are linked not just through the movements of people and flows of money and goods, but also through the constant exchange of information via modern forms of communication, now primarily the Internet. See Vertovec (2009) for a concise introduction to a complex literature. Migrant families, in addition to receiving remittances, may be in constant contact with their relatives in destinations about what to do with those remittances. They can also act as a source of emotional and material support for their relatives in destinations, perhaps to the extent of receiving, in times of need, reverse remittances in cash or kind. Origins and destinations thus become intimately linked in transnational flows that allow parties in both origins and destinations to participate in each other's lives and in the lives of others in both areas, locally and more widely.

The transnational community has been seen as a way to reconcile opposing views of migration and development (Portes, 2009): between those who see migration as positive for development, through remittances and as a way out of unemployment and poverty on the one hand, and those who view migration as negative for development through brain drains, skill losses and the origins becoming subservient to destinations on the other. Nor does successful integration into

destination areas appear to prejudice continued economic, social, and even political involvement in areas of origin. Hence, the transnational community is a form of 'globalization from below' that can promote development through the constant interaction of people, money, and ideas (Portes, 2009: p. 10). Whether this interaction can continue through subsequent generations as migrants and their descendants become progressively more settled in the destination is unclear and will be further addressed below in the context of diaspora engagement. The transnational perspective is also seen to provide a vehicle through which to reconceptualize critically our thinking on migration and development within a global system of power relations (Faist, 2010; Glick Schiller, 2010). Certainly, almost by definition, the analysis of international migration forces the analyst to think beyond the nation state to those transnational institutions that both generate and channel movement in particular ways. However, perhaps more than anything, the transnational perspective has brought a critical perspective to the discussions of migration and development.

Managing Migration for Development

Migration was seen, perhaps still is seen by some, to be brought about by a lack of development. People left because of a lack of opportunity at home. However, if such opportunities could be generated through a development program, then migration would cease. Hence, migration should slow consequent upon development. The experience has proven quite the reverse: migration tends to be positively associated with development. Education programs increase aspirations and agricultural improvement or industrial employment should provide increased income, and so development gives both potential internal and international migrants the information and the means through which to move. The volumes of remittances discussed earlier and revisionist interpretations of skilled migration away from brain drains drew attention to the transformative aspects of migration. Views on migration shifted from seeing migration as something undesirable and negative to accepting that migration could play a positive role in development. The epicenter of this change can be dated to the last decade of the twentieth century, even if many of the ideas originated much earlier. Within the context of this shift, it was but a short step to the idea that migration could be managed to bring about specific positive development outcomes and, consequently, migration and development as a topic has risen toward the top of the policy agenda at the international level.

Two other factors have contributed to the emergence of international migration as a serious policy concern. The first is what might be termed the 'tactical reason.' Migration into a country is considered the concern of the admitting state alone. Hence, governments see little reason to debate an issue for which they feel that they have sole responsibility, or, if pushed, should discuss only bilaterally with origin countries. However, it has become clear that a forum to discuss migration is useful, where countries can meet collectively to share experiences and to deal with sensitive matters such as irregular migration. While migration itself is a sensitive topic that cannot often be discussed overtly, if linked with development it gives the pretext to allow countries to discuss these matters in a somewhat different context. The current composition of delegates to the Global Forum on Migration and Development (GFMD) reflects this bias: officials with responsibility for migration control dominate the government representatives, with very few development specialists in attendance. The GFMD is largely a *de facto* forum on migration rather than a migration and development meeting and until the development community begins to take migration seriously as an issue, it will continue to be so.

The second reason is that very real and pressing matters exist in current global flows of migration. The trafficking and smuggling of people are high on the agenda, made more pertinent by the number of deaths among those attempting to cross the Mediterranean to Europe during the latter half of 2013. The protection of migrant workers is another central concern, an issue of longstanding interest to the International Labour Organization of the United Nations. This work extends into the area of labor recruitment, the often excessive fees that are paid, and the abusive conditions workers face, both during their recruitment and at destinations. The whole issue of migrant rights is central to these concerns. However, fundamentally important though these matters are to migrants, they do not deal centrally with migration and development. Two concerns, however, do fall squarely into this category: remittances and 'leveraging' the diaspora.

Remittances

The global patterns of flows of remittances were discussed above. Some doubts were expressed whether remittances, from international sources at least, reached the poorest people in the poorest parts of a country. While remittances do impact positively upon those who receive them, helping to reduce poverty and improving education and health, that impact may be more modest than might have been anticipated. Considerable heterogeneity among countries exists, with the data from about half of the 11 countries in a large survey in Latin America suggesting no significant impact on poverty (Acosta et al., 2007). Although the impact of remittances on development may still be variable and contested, two points seem clear. First, remittances are private monies that belong to migrants and their families. Governments would be unwise to attempt to tax or guide their use in any way and most migrants make good use of their remittances for education, subsistence, or housing. No clear dividing line between investment and consumption uses seems either practical or meaningful in this regard. Second, the international community can act to reduce transaction costs of sending remittances. Considerable progress in some migrant corridors seems to have been made, but much still remains to be done in the poorest parts of the world in Africa (World Bank, 2013).

Diasporas

In the diaspora, or the community of overseas migrants and their descendants, is to be found a pool of highly skilled and

often wealthy people that can be 'leveraged' (the term of the World Bank) to return on a short or longer-term basis and invest in their homeland. Nevertheless, it is difficult to separate change brought about by returnees from more general change in the origin economies. Migrants will only return home when something exists for which to return. The cases of arguably the more successful diaspora contributions, China and Vietnam, were consequent upon reforms in the investment and political climate at home.

The danger with both diaspora engagement and remittances is that the responsibility for development may be transferred to the migrants and away from the state. Nevertheless, the state involvement has to be various, variable, and tailored to the specific circumstances of the area and country, which should allow space for bottom-up approaches through diaspora engagement. The migration of skilled people back to their home areas to support training or entrepreneurial activities, even if for short periods, seems one avenue that policy makers could pursue with profit, and circular migration has certainly emerged as an area of recent policy interest.

The principal weaknesses of the diasporas as development agents revolve around their highly heterogeneous nature, full of competing interests that make significant and sustained development projects, even at local and regional levels, problematic. While the debate on the effectiveness of unplanned versus planned development continues (Rigg, 2012), it seems unlikely that the diaspora will be a major agent of change in bringing development. That said, it must always be recognized that many of the great leaders of revolutionary change in the twentieth century learned their ideologies and practices in the diaspora. Nevertheless, the jury is still out on whether migration can be effectively managed for development. The pendulum that has seen migration swing from being seen as negative for development to being positive may now be swinging back (de Haas, 2010, 2012).

The International Architecture for the Management of Migration and Development

No United Nations organization exists with primary responsibility for migration and, until 2007, no international forum existed in which to have discussions on the issues at the multilateral level. United Nations agencies exist with primary responsibility for definite types of population movements: the United Nations High Commissioner for Refugees for international forced migrants, and the International Labour Organization for labor migrants. Neither is particularly concerned with migration and development, although remittances are central to issues of labor migration. An international organization, the International Organization for Migration acts as a *de facto* global clearinghouse for issues in migration and development. However, it works with United Nations bodies, particularly the Population Division of the Department of Economic and Social Affairs of the United Nations in New York, the Regional Commissions of the United Nations, and the World Bank, and with a number of supporting civil society organizations, perhaps most particularly the Migration Policy Institute in Washington. The United Nations itself, after widespread consultations, in 2005 and 2006, recommended that the GFMD should be established, and it held its first meeting in 2007. The GFMD is a country-led, non-binding body that meets annually to discuss key areas in migration and development. However, as stressed above, a greater involvement of development experts and policy makers with responsibility for development will be required if this forum is to achieve its mandate.

Conclusion

That migration and development are associated seems incontrovertible. That changes in specific dimensions of what we can consider to be development, such as transportation and education, will bring about shifts in migration is also clear. However, given the sheer complexity of all the variables that impinge on what we call 'development,' migration is but one in this 'nexus' of change. Whether migration can be managed in order to maximize the benefits to development and minimize the risks of moving is not at all so clear. One looming threat is the impact of environmental change on development: whether rising populations and their carbon emissions will produce such catastrophic change that civilization as we know it is unlikely to survive. Totally different viewpoints still exist even about the least uncertain of the many unknowns facing future development, global population growth. Contrasting Emmott's pessimism (2013) with Dorling's optimism (2013), for example, shows the depth to which opinions on this topic of population–environment linkages are still divided some 200 years after the writings of Thomas Malthus.

How future global development in the face of environmental change will impact upon migration is a much greater unknown. Despite predictions that hundreds of million of people will be displaced by rising sea levels, desertification, salinization, extreme climatic events, lowered agricultural production, and wars from increasing competition for scarce resources, the most objective assessment to date is less alarmist (Foresight, 2011). The report stresses the difficulty of separating an 'environmental' driver from those other economic, social, and political factors that cause people to move. While we may expect increased numbers of people to be displaced, the majority will be more likely to move locally and over the short term rather than globally and permanently. The plight of those left behind will be as great a development challenge as the number of those displaced. The largest migration in history (Saunders, 2010), the movement to urban areas, which is driven primarily by factors other than environmental change often brings people into environmentally more hazardous areas in coastal zones around the great megacities of the world. However, the development challenges of these cities have not been a central concern in the migration and development debate.

The introduction of displaced people into the discussion leads to one of the weakest areas in the migration and development debate, the issue of migration and political development, how population movements shift over the long term as a consequence of the evolution of the state and its institutions. An important subset of this migration is forced migration for

political reasons. Refugees were not part of the Zelinsky, longue durée, hypothesis with which this discussion began. Yet, recent scholarship has begun to examine the impact that changing age structures, and particularly the existence of a 'youth bulge,' have on conflict and the emergence of liberal democracies (Cincotta, 2009; Goldstone et al., 2012). The extent to which migrants play a role in disseminating competing ideologies transnationally and between urban and rural has yet to be fully elucidated. Clearly, improving education levels that change aspirations, as well as improvements in gender relations, and the diffusion of modern forms of communication are also fundamental to the mix, but the movements of people are both important causes and consequences of conflict. A search for linkages with the broader demographic transition may prove fruitful.

Finally, the framework in which migration and development tends to be viewed is problematic. It sees development as essentially flat in a simple bipolar division of the world into 'North' and 'South,' as if a simple division between developed and developing exists. Not just the BRICS (Brazil, Russia, India, China, and South Africa) and their impact in their respective regions, but also the emergence of a range of other economies in Africa, Asia, and Latin America have generated a highly heterogeneous global economy. The BRICS themselves cover very different economic and political systems, as does a blanket category such the 'North.' In terms of migration, for example, significant differences exist between the settler societies of North America and Australasia and the longer-established developed economies of Europe. Until both academics and policy makers move beyond simple categories such as South–South migration, the real linkages between migration and development, both theoretical and policy, will prove elusive.

Given that migration is an integral part of development itself, it seems that the starting point needs to be development and how migration is likely to vary as development and development policy change. This is most likely to be context-specific, within region and even within country. Nevertheless, the great macrolevel shifts in mortality and fertility, as well as the transition to an urban society, will provide the common themes around which the variation revolves. Once the development can be mapped, the migration can be anticipated and plans made accordingly. Thus, the emphasis shifts from migration and development to development and migration (also DeWind and Ergun, 2013).

Migration and Fertility

Abstract

Until recently, the growth and structure of national populations has primarily been understood in terms of fertility and mortality, with most classic demographic indicators assuming populations to be closed to migration. This assumption is obviously no longer tenable; most developed countries have relatively low mortality and fertility concurrent with relatively high levels of international migration. These trends highlight the need to more systematically incorporate population mobility into studies of reproduction and growth. This article discusses the mechanisms by which mobility and immigration are linked to fertility, assesses various lines of theorizing about these links, and reviews current research literature.

Until recently, the growth and structure of national populations has primarily been understood in terms of fertility and mortality, with most classic demographic indicators assuming populations to be closed to migration. This assumption is obviously no longer tenable; most developed countries have relatively low mortality and fertility concurrent with relatively high levels of international migration (Preston and Wang, 2007; Mitra, 1990; Morgan et al., 1994). These trends highlight the need to more systematically incorporate population mobility into studies of reproduction and growth. International migration can affect population reproduction through two main mechanisms. The first is in- and out-migration itself. Net flows of immigrants directly impact both the size and age structure of receiving populations. Several studies have investigated how to incorporate this effect into classic demographic expressions. A general elaboration was provided by Preston and Coale (1982) who showed that in the steady-state models that form the core of formal demography, the assumption of a closed population could be relaxed by including age-specific migration rates in addition to age-specific fertility and mortality rates. The overarching insight was the recognition that age-specific migration rates affect cohort size in a manner analogous to the effect of age-specific mortality rates, and thus can easily be incorporated into demographic analyses. Several variations of this general approach have been developed in the literature (Espenshade et al., 1982; Espenshade, 1986; Blanchet, 1989; Cerone, 1987; Mitra, 1983; Preston and Wang, 2007; Schmertmann, 1992).

The second mechanism through which migration can affect population is via the fertility of immigrants at destination (Bledsoe et al., 2007; Jonsson and Rendall, 2004; Parrado, 2011; Parrado and Flippen, 2012; Toulemon, 2004). Despite its importance, the connection between immigration and fertility has received far less attention and our understanding of the interaction remains limited and imprecise. This is problematic because births to immigrant women can be an important component of population reproduction, especially if the fertility of immigrants differs significantly from that of natives. In an early discussion of alternative paths to a stationary population in the United States, Coale (1972) highlighted the interaction between fertility and immigration in producing a constant number of annual births. However, the need to consider the fertility of immigrants when assessing current and future population dynamics is generally not recognized in widely distributed population reports, including most population projections.

In addition to the importance of births to immigrant women for population growth, a main focus of this article is elaborating on the extent to which fertility and migration are linked. Most prior analyses assume the two processes are independent. However, a handful of studies in Europe (Andersson, 2004; Toulemon, 2004) and among Hispanic and Mexican women in the United States (Lindstrom and Giorguli Saucedo, 2007) have documented that fertility patterns among immigrant women are shaped by the experience of migration itself. In particular, migration alters the age pattern of childbearing in ways that are complicate common period measures of fertility. Among immigrant Hispanic women, for instance, fertility is often depressed in the years immediately prior to migration and accelerated in the years immediately following migration *irrespective of age* (Parrado, 2011; Parrado and Flippen, 2012). The main insight is that for immigrant women *two time dimensions* (rather than age alone) define childbearing trajectories at destination: age at migration and time at destination. Age at migration initiates the exposure period for childbearing in the foreign country, and time abroad defines childbearing trajectories over time. Standard demographic measures based on nonmigrant populations do not account for the association between migration and childbearing. As a result, they produce systematically biased estimates of fertility levels (Bledsoe et al., 2007; Frank and Heuveline, 2005; Lichter et al., 2012; Parrado and Morgan, 2008). These biases directly affect our understanding of immigrant fertility and its contribution to nations' total population growth. Moreover, given growing immigrant representation, they affect estimates of fertility levels for the receiving country population as a whole and especially for specific racial/ethnic groups – fueling in some cases racial and ethnic stereotypes.

In this article, I elaborate the substantive and methodological implications of the connection between immigration and fertility and empirically illustrate its importance in the U.S. case, including the implications for understanding changes in the U.S. fertility rates after the 2007 recession.

The Link between Immigration and Fertility

A concrete examination of the two time dimensions linking migration and fertility, namely age at migration and time in

the United States, and their effect on fertility measures highlights the problem. To be precise, fertility level in this article refers to the number of children women have, also referred to as *quantum*, as distinct from *tempo* that refers to the age pattern of childbearing. The most common measure for assessing the fertility level of a population at a point in time is the period Total Fertility Rate (TFR), which is an *estimate* of the number of children a woman would have *if* she were to experience the age-specific fertility rates (ASFRs) observed in a particular period and survive from birth through the end of her reproductive life. The ASFRs describe the population's age pattern of childbearing. They are obtained by dividing the number of births to women of a certain age by the total number of years at risk for this population. These ASFRs are then aggregated to calculate the TFR.

Formally, the TFR for year t can be written as:

$$TFR(t) = \sum_x f(x,t) = \sum_x (B(x,t)/N(x,t)) \qquad [1]$$

where $B(x,t)$ equals the number of births to women aged x at time t and $N(x,t)$ is the number of women aged x at time t. The index of summation x ranges over all childbearing years. It is a *hypothetical* measure based on rates, and does not correspond to the actual behavior of any identifiable group or cohort. Rather, it relies on the assumption that the age-specific rates in a given period will remain steady, and thus approximate the lifetime trajectories of actual birth cohorts. An alternative, and arguably a more accurate, measure of fertility level (Ryder, 1980) is the average number of children ever born (CEB) at the end of a woman's reproductive period, usually after ages 40–44. CEB summarizes actual rather than hypothetical childbearing and is an exact representation of the number of children that actual cohorts of women have borne. The main limitation of CEB is that it reflects the experience of past cohorts and thus provides little information about fertility levels among younger women or at a point in time. In part for this reason, the TFR has become the most common measure used for describing the fertility level of a population.

However, it is clear that meaningful and precise ASFRs are critical for both obtaining a TFR that correctly measures fertility levels and accurate population projections, since the expected number of births (the new cohort) is obtained by first multiplying the size of the female population at given ages by the estimated ASFRs and then summing these products. It has long been recognized, however, that when childbearing ages are in flux, ASFRs are a poor approximation of actual fertility levels understood in terms of number of children or family size. For instance, in discussing the implications of the widespread use of fertility control for period fertility measures, Hajnal (1947) concluded that when women can time their fertility "a change in the rate at which people are having children in a given year can no longer be taken as an indication of a change in the number of children they will bear altogether in the course of their reproductive lives" (p. 143). Some of the most important work on the American baby boom (e.g., Ryder, 1980) and on lowest-low fertility (e.g., Bongaarts and Feeney, 1998; Kohler and Ortega, 2002; Schoen, 2004) addresses this distinction between 'quantum' and 'tempo.'

The direct application of fertility measures, such as the TFR, to immigrant women ignores the potential impact of characteristics unique to immigrant populations on period fertility estimates. Immigrants' life-course transitions are divided between sending and receiving countries. Depending on the age at migration, their childbearing can take place completely at origin, completely at destination, or in a mix of both. Thus, as a group, their completed fertility will almost invariably be different from their fertility contribution to host societies, since the latter includes only the children they have in the receiving context. Moreover, the age pattern of childbearing is often powerfully shaped by the event of migration itself. For hypothetical measures such as the TFR to be a meaningful indicator of family size, this implies that they will have to be reformulated, capturing cohorts' experiences of both migration and childbearing. Moreover, if there is a close association between the event of migration and childbearing, we can expect potentially large distortions in ASFRs, which would result in inaccurate assessments of immigrant fertility.

A common situation documented in various migration streams is the case where childbearing tends to occur shortly after migration. **Figure 1** simulates this effect by plotting ASFRs (dotted curve) and fertility rates since time of migration (solid curves). The x-axis corresponds to women's age and the y-axis to fertility rates. The dotted lines crossing the x-axis correspond to different ages at migration. Thus, the figure captures the two time dimensions discussed above: age at migration and time at destination, and their association with fertility. The case illustrated in **Figure 1** corresponds to the situation where ASFRs peak during the years shortly after settlement (vertical dotted lines) and then rapidly decline with time at destination (the different solid curves). Since this pattern is reproduced *irrespective of age at migration*, failure to control for the interaction between migration and fertility inflates ASFRs (dotted curve) that remain artificially high throughout a large portion of reproductive ages. However, rather than the product of fertility behavior, high ASFRs are the result of the continued influx of immigrants and the concomitant higher fertility rates in the years after migration. For assessing the level of immigrant fertility, a main implication is that no birth cohort will reproduce the observed ASFRs. They are only applicable to migrant cohorts as they age at destination. For the dynamics of population reproduction, the main implication is that immigration and fertility rates are not independent; a change in immigration will produce a change

Figure 1 Simulation of fertility rates by age at migration and by time in the United States.

in fertility rates, and demographic techniques should be able to separate those two effects.

This phenomenon – a rise in birth rates following a major event – in many ways parallels for the experience of the baby boom. When World War II ended, young women faced fewer constraints to childbearing and began their families earlier, but older women's fertility also rose, as they bore children that had been postponed during the conflict. Thus, while fertility rates rose substantially, period estimates, which cannot distinguish between timing and quantum changes in fertility, badly overestimated the increase relative to cohort measures (see Ryder, 1980, 1983, 1986). As applied to the immigrant case, the pattern has been corroborated among Hispanic, especially Mexican, immigrants in the United States and among immigrants in Europe (Parrado, 2011; Parrado and Morgan, 2008; Toulemon, 2004).

It is important to note, however, that while the association is common to the general immigrant experience rather than just the experience of one particular ethnic group, the magnitude of the association as well as its effect on fertility estimates is likely to vary across contexts and groups. Assessing potential variation is central to discussions about racial, ethnic, and national origin differences in fertility behavior. However, it is not our intention to explain this variation. Such exercise requires paying attention to migration dynamics across the life-course, the socioeconomic composition of immigrant flows, and issues of immigrant incorporation. Our objective is more limited: to document and elaborate on methodologies that can account for the association between migration and fertility and assess its significance in the U.S. context. To the extent that the association is general to immigrants rather than specific to particular ethnic or national origin groups, then there are reasons to focus on the immigrant component of population growth irrespective of ethnic or of national origin in demographic analyses. At the same time, if national origin differences are salient, fertility will be affected by both the changing composition of the immigrant flow as well as changes in the overall number of immigrants.

Fertility at Origin and Destination

To more precisely separate population growth that stem from immigration per se from the fertility contribution of immigrant women, it is important to start with the recognition that the immigrant fertility takes place both at origin and destination. Measures such as CEB capture completed fertility but provide no information about where childbearing takes place. However, from a receiving country perspective, the fertility-specific contribution of immigration refers solely to the children of immigrant women born at destination. Children born abroad would also contribute to the receiving country population if they move with their parents. However, they contribute through immigration rates, not through fertility. For some analyses, such as discussions about fertility decline, the distinction might not be relevant, since researchers might be interested in focusing on the total number of children immigrant women have. From a population perspective, though, the distinction is important since it refers to the sources of reproduction. For receiving countries, the fertility component of population growth refers only to children born at destination. Technically, the decomposition can be represented in the following way:

$$\mathrm{CEB}_{(\mathrm{lifetime})} = \mathrm{CEB}_{(\mathrm{at\ origin})} + \mathrm{CEB}_{(\mathrm{at\ destination})} \qquad [2]$$

Thus, we are interested in obtaining precise estimates of CEB at destination. The decomposition would be straight forward if we had information on children's place of birth for women who have completed their reproduction, ages 40–44. However, obtaining period estimates of children born at destination requires taking into consideration the two time dimensions discussed above, namely age at migration and time in the receiving country. The destination-specific total fertility rate (D-TFR) is a modified version of the standard TFR that takes into account age at migration and time in the United States to avoid the problems arising from migration-related disruptions in the age pattern of childbearing (Toulemon, 2004; Parrado and Flippen, 2012). The D-TFR is computed by first calculating duration at destination-specific fertility rates (DD-FRs) in a particular year for women migrating at a certain age. DD-FRs are obtained by dividing the number of births among women with certain duration at destination by the total number of women with the same duration in a particular age-at-migration cohort. Specifically.

$$\text{DD-FR}(x,a,t) = B(x,a,t)/N(x,a,t) \qquad [3]$$

where $B(x,a,t)$ equals the number of births to women with time x at destination, age a at migration, and in year t. $N(x,a,t)$ is the number of women with time x at destination, age a at migration, and in year t. Aggregating the DD-FRs over time at destination (x) for specific migration cohorts (a) in a given year (t) produces an estimate of the accumulated fertility over time at destination of particular age-at-migration cohorts. Once the cohort reaches ages 40–44, which corresponds to different durations in the receiving country depending on age at migration, then the cumulative DD-FRs becomes an estimate of the total number of children women migrating at certain ages will bare at destination if they are subject to the DD-FRs observed for migrating cohorts in a particular period. The actual childbearing experience of age-at-migration cohorts is again given by the completed fertility rate ($\mathrm{CEB}(x,a,t)$) that measures the average number of children after x time at destination that women migrating at a certain age a actually had at time t.

Aggregating across migrating cohorts (a) and weighting by their proportional representation in the pool of immigrant women yields the D-TFR(t), which provides an estimate of the number of children that all immigrant women will have at destination if they are subject to the average U.S. DD-FRs and age at migration rates observed at a particular point in time. This can be written as,

$$\text{D-TFR}(t) = \sum_a \sum_x \text{DD} - \text{FR}(x,a,t) \times p(x,a,t) \qquad [4]$$

where $p(x,a,t)$ equals the proportion of immigrant women with time x in the United States, age a at migration, and in year t. D-TFR(t) is then a period estimate of the number of children immigrant women would have at destination given prevailing patterns of migration and childbearing, which corresponds to $\mathrm{CEB}_{(\mathrm{at\ destination})}$ in eqn. [2]. In the next section, we apply these measures to the U.S. context.

Immigrant Fertility in the United States

The United States is an apt setting for illustrating the interaction between migration and fertility. Drawing on multiple data sources, we can calculate the measures presented for immigrants overall, as well as by race/ethnicity and country of origin. Our analysis pays particular attention to the Latino experience since the purportedly abnormally high fertility of Latina women is often raised in discussions of socioeconomic incorporation and a central dimension undergirding negative stereotypes of the group (Chavez, 2012; Parrado and Flippen, 2012).

Table 1 pools data between 2003 and 2004 American Community Surveys to report the distribution of women of childbearing ages 15–44 and birth rates by race, ethnicity, nativity, and country of origin. Results highlight the magnitude of the fertility contribution of immigrants relative to natives as well as the significance of immigrant fertility for monitoring the demographic profile of the U.S. population. For the population as a whole, results show that 78.7% of births in the United States are attributable to native women, which is 4.3% points lower than their representation in the total population (83.1%). Alternatively, almost a quarter (21.3%) of U.S. births is attributable to immigrant women, even though they represent only 16.9% of the female population in childbearing ages.

The pattern is also evidenced, with variation, when we separate women and births by race/ethnicity. Without distinguishing by nativity, results show that while non-Hispanic (NH) white women represent 65.4% of the U.S. population, they accounted for only 59.9% of births. Thus, NH white women's share of births is 5.5% points lower than their representation in the population as a whole. At the other extreme, Hispanics represented 14.8% of the U.S. population but 19.7% of all births (difference = 4.9). In fact, more births relative to population are evidenced across all minority groups, illustrating the contribution of fertility to the growing diversity of the U.S. population.

Separating women and births by nativity more precisely assesses the sources of these patterns. Natives overall are significantly underrepresented in births (difference = −4.3). This is particularly the case for NH whites but also holds for Asians. More importantly, the greater representation of births to Hispanic and black women is considerably lower among natives. Among Hispanics, the overall difference is reduced from 4.9% overall to 1.3% among natives. The most salient result from Table 1 is that most of the growing diversity of U.S. births stems from the fertility contribution of immigrant women. The higher contribution is particularly pronounced among Hispanics, but is evident across all ethnoracial groups. Result show that even though foreign born Hispanic women comprise 8.1% of the U.S. female population of reproductive ages, they accounted form 11.6% of births. However, while percent differences are much lower, even the fertility contribution of immigrant NH white women is higher than their share of the total population, and the same can be said of NH black and Asian women.

To further highlight its importance, the last column of Table 1 reports the within-group odds ratios of the likelihood of a birth occurring to an immigrant compared to a native woman. To illustrate, in the case of Hispanics, this is computed as the percent of births to immigrant women (11.6) divided by the percent of immigrant women (8.1) divided by the percent of births to native women (8.1) divided by the percent of native women (6.8). Odds ratios also account for the bounded nature of percentages and their limitations for group comparisons. Results from this calculation show that the fertility contribution of immigrant women is much higher than natives in the population as a whole and for all groups. Overall, results show that a child born in the United States today has a 32% higher chance of being born to an immigrant than U.S. born woman (odds ratio 1.32). Among NH whites, the estimated odds ratio of 1.13 implies that a white child has a 13% higher likelihood of being born to an immigrant than a native woman. The

Table 1 Distribution of 15–44-year-old women and births by race/ethnicity, country of origin, and nativity in the United States

American Community Survey 2003–04.

likelihood of immigrant origin birth is highest among Asians (1.51) and is 1.20 among Hispanics. The main implication is that the growth of the U.S. population overall and the relative growth of ethnoracial groups is powerfully shaped by the fertility of immigrants.

It is important to consider, however, that pan-ethnic and racial categories mask considerable variation in national origins among the immigrant population. Focusing on the largest immigrant groups, the bottom panel of Table 1 replicates the preceding calculations for Mexican, Cuban, Dominican, Chinese, Korean, and Filipino origin populations. Results further document the salience of immigrants for fertility within national origin groups. In most cases, the share of births born to immigrant women is higher than their share of the total U.S. population, particularly for Mexicans. The percent of births to Mexican immigrant women is 2.1% points higher than their representation in the population. However, it is also higher for Chinese (0.1). The odds ratio estimates again highlight the salient contribution of immigrants for within-group fertility. In all cases, within national origin groups, U.S. births are more likely to occur to immigrant than native women and group differences do not always follow estimates obtained from difference in percentage comparisons.

As elaborated in the theoretical section, it is not obvious that over representation in births, i.e., higher birth rates, among immigrants imply higher fertility levels or larger family sizes. We investigate the distinction for the U.S. case in Table 2. Pooling data from the June supplements of the Current Population Survey for the years 2000–08, which contain information on births during the prior year as well as total number of CEB, the table compares estimated fertility levels obtained from the standard TFR measure and CEB among women aged 40–44 by native and race/ethnicity. Despite the differences between the two measures, when we focus on U.S. born women, the period TFR and cohort CEB estimates are largely consistent; for all native women, the TFR is only 0.1 children higher than CEB. The consistency in estimates across measures is also evident when we separate women by race/ethnicity. In all cases, the difference between period and cohort estimates is negligible among native born women. Results support the expectation that as a hypothetical measure, the TFR is a good approximation to actual fertility levels for U.S. born women.

Table 2 TFR and CEB by race/ethnicity and nativity

	TFR (1)	*CEB*[a] *(2)*	*Difference TFR − CEB (3)*
Native	2.03	1.88	0.10
NH white	1.90	1.84	0.06
NH black	1.99	1.99	0.00
Asian/Pacific Islander	1.69	1.91	−0.22
Hispanic	2.21	2.13	0.08
Foreign-born	2.59	2.13	0.46
NH white	2.21	1.83	0.38
NH black	2.37	2.03	0.34
Asian/Pacific Islander	2.20	1.85	0.35
Hispanic	2.95	2.49	0.46
All race/ethnic groups	2.11	1.91	0.20
White, non-Hispanic	2.02	1.84	0.19

Asian/Pacific Islander	2.00	1.86	0.14
Hispanic	2.58	2.36	0.22

[a]Among women ages 40–44.
June Current Population Survey (CPS) 2000–08.

Results differ dramatically, however, among immigrant women. Overall, the TFR exaggerates the fertility level among the foreign-born by 0.5 children compared to the actual number of CEB. Moreover, there are few differences across racial and ethnic groups. The pattern observed for immigrant Hispanics is also reproduced among NH white, NH black, and Asian immigrants. For instance, among NH whites, the TFR is 0.4 children higher than the actual CEB. Interestingly, comparing the CEB of natives and immigrants within ethnoracial categories shows relatively modest differences for all groups except Hispanics, since they originate in higher fertility countries than their white and Asian counterparts. However, consistent with the expectation of a distortion in period rates resulting from an association between migration and childbearing, the TFR is consistently much higher and the disparity between period and cohort measures more pronounced among the foreign-born of all ethnoracial groups.

An associated problem is that given the growth in immigration levels over the past several decades, the TFR could be distorting fertility estimates both for the U.S. population as a whole and for particular racial/ethnic groups. The bottom panel shows that except for NH blacks the TFR is higher than CEB for all groups, supporting the concern that the failure to account for timing distortions among immigrants is inflating fertility estimates by race/ethnicity. Moreover, even for the United States as a whole, the 2.1 estimated TFR is 0.2 children higher than the 1.9 CEB. To magnify the disparity, the 10% overestimate in the TFR means that *if immigration were to stop immediately*, applying conventionally calculated fertility rates in population projections would overshoot the annual number of births just among U.S. born women by 300 000 every year.

These results illustrate the potential importance of systematically separating immigrants from the native population in studies of fertility. They also suggest that, despite stereotypical representations, the issue is not unique to Hispanics. Table 3 focuses specifically on the Hispanic experience and separates CEB from children born in the United States according to eqn. [4]. The table reports US-FRs (eqn. [3]), US-TFRs (eqn. [4]), CEB, and the difference between the US-TFR and CEB for Hispanic immigrant women obtained from the 2000–2008 CPS according to age at migration (a) and time in the U.S. (x). Results document that US-FRs tend to be higher during the years immediately following migration, especially for women migrating after age 20, and then decline. This is consistent with the expectation of disruption in the timing of childbearing associated with migration. The US-TFRs that accumulate the duration-specific fertility rates provide a period estimate of the number of children born to women migrating at different ages after particular durations in the United States. Results show that after 20 years of U.S. residence, near the end of their reproductive ages, women migrating between ages of 15–19 have had 2.63 children in the United States. This is almost identical to the actual

June Supplement, Current Population Surveys 2000–08.

number of CEB. Among this migrant cohort, the difference between US-TFR and CEB is very close to zero; as could be expected, the difference does not change with U.S. duration since it represents the number of children born before migration. The main implication is that for young migrating cohorts (15–19) most of their childbearing takes place in the United States.

As the age at migration increases, the difference between US-TFR and CEB also increases. For women migrating between 20 and 24 years of age, results show a US-TFR of 1.99 after 16 years in the United States, which is roughly 0.5 children lower than the CEB. In other words, among women in this migration cohort roughly one-half child was born at origin. The difference for women migrating between 25 and 29 years of age is 1.03. These women average only 1.3 children at destination after 15 years of U.S. residence, even though their completed fertility is 2.3. Later ages at migration result in fewer U.S. born children. At the extreme, women migrating at ages 40–44 bare only 0.07 children in the United States, even though their completed fertility is 2.54 (not reported).

The US-TFR computed by aggregating across migration cohorts, according to time in the United States, provides an estimate of immigrant women's total number of U.S. born children and is reported in the last columns of the bottom panel of **Table 3**. The estimated US-TFR for immigrant Hispanic women after 19–20 years of U.S. residence is 1.94, which is *1 child lower* than the 2.96 estimate obtained applying the standard method of calculating TFR (eqn. [1] and reported in **Table 2**) to this population. Again, we argue that the main source of the disparity is the failure of the TFR to account for the interaction between age at migration and time in the United States in affecting period fertility measures among immigrant women. This overestimation misrepresents the fertility experience of immigrant-origin groups and produces biases in population projections, hence the need for more precise measures. As the Hispanic case demonstrates, the main implication for demographic analysis is that standard measures overestimate the fertility contribution of immigrant women to countries of destination. For discussion of racial and ethnic differentials in fertility behavior, the overestimation misrepresents the experience of groups with sizable immigrant representation, such as Hispanics.

The 2007 Recession and Fertility in the United States

The difficulty in integrating immigration and fertility into explanations of population dynamics in host societies, is especially relevant for discussions of the connection between fertility and economic fluctuations. A recent report by the Pew Research Center (2012) as well as official statistics from the National Center for Health Statistics (Sutton et al., 2011) documented a sharp decline in U.S. fertility rates after the 2007 economic recession (approximately 8%). The finding is generally not surprising since economic recessions have historically been associated with lower fertility. However, the reports show considerable variation across groups in the impact of the recession on fertility. In particular, the Pew Research Center reports that the decline was especially pronounced among immigrant women (14% relative to only 6% among U.S. born women). The effect is even more salient among Mexican immigrants, who saw their fertility rates decline by 23% after the recession.

The dramatic disparities in the apparent impact of the recession across groups garnered significant interest in both popular and academic circles, with a wide array of cultural and structural explanations proffered. Whatever its source, it was widely assumed that a change in behavior was at the heart of falling fertility. For instance, the Pew report emphasized that "the fall in the number of births to women is explained by behavior (falling birth rates), rather than population composition (change in the number of women of childbearing age)" (p. 3). As another example, the *New York Times* reported the decline and difference by group as a surprising change in Latino families. Reinforcing both the erroneous expectation of large Latino families and the confusion between fertility rates and family size, the opening sentence of the news report stated: "Hispanic women in the United States, who have generally had the highest fertility rates in the country, are choosing to have fewer children" (NYT, 2012) and demographers were quoted as saying: "It is surprising…When you hear about a decrease in the birthrate, you don't expect Latinos to be at the forefront of the trend." The problem is not that rates did not decline, but that the attribution of the change to a dramatic reorientation of the high fertility preference of Latino women does not account for the population processes producing the change.

Our theoretical and methodological connection of immigration and fertility provides a different, more demographic account. The fertility level of Latina women in the United States hovers between 2 and 2.5 children. So, desire for smaller families is something well-entrenched in Latino family orientations. Recessions do affect fertility rates, but there are no obvious reasons that they should affect the fertility decisions of Latina women more so than for other groups. In fact, rather than a change in Latino fertility, what specifically and dramatically declined are the fertility rates of all immigrants, including Latinos. Ignored in the Pew and media accounts is the fact that the recession also resulted in a dramatic drop in immigration to the United States. The combination of deteriorated economic climate, significant voluntary and involuntary return migration to Mexico, and border enforcement policies changed migration flows after the recession. In fact, many migration scholars have argued that with the recession net migration from Mexico to the United States is close to zero or even negative (Pew Hispanic Center, 2012). Since, as we argue, immigration and fertility rates are connected, the change in immigration rates is of central importance to understanding fertility rates. More specifically, since immigration coincides with family formation, with a large portion of immigrant fertility taking place soon after arrival, declining immigration rates will also reduce the representation of the group of immigrant women most prone to have children. In other words, the reduction in immigration is affecting the composition of the immigrant population, increasing the representation of long-term residents who are more likely to have completed their fertility, and reducing the contribution of new arrivals who are more likely to have children. The main hypothesis then is that rather than the product of changing ideas about family size, the decline in the fertility rates of immigrants after the recession is primarily the outcome of declining immigration rates.

Figure 2 Birth rates for foreign-born Mexican women according to years in the United States.

An empirical examination corroborates this argument. Data from the 2005–06 and 2010–11 American Community Survey confirm the findings of prior reports; the birth rate for immigrant Mexican women in the United States declined 12% after the recession, from 110 to 69.9 children per 1000 women (15–44). Accounting for time in the United States and computing the duration at DD-FRs shows a very different pattern of change in fertility rates. Figure 2 reports DD-FRs for foreign-born Mexican women before and after the recession by U.S. duration. If behavioral changes were responsible for the drop in immigrant fertility rates, then we would expect somewhat parallel DD-FRs curves with much lower rates after the recession irrespective of time in the United States. Instead, the figure shows that the DD-FRs of immigrant women changed little before and after the recession; the relationship between U.S. duration and birth rates remained largely consistent over time. Only among women with 6–10 and 11–15 years in the United States do we see a 10 and 7% decline in fertility, which is comparable to the impact of the recession on native and NH women.

It is worth emphasizing that the lack of obvious change in DD-FRs coincides with a dramatic change in the composition of the immigrant population according to U.S. duration. Figure 3 plots the share of foreign-born Mexican women in the United States according to U.S. duration. The figure illustrates the impact of declining immigration during the recession on the composition of the foreign-born Mexican population. The share of immigrant women with 0–5 years in the United States declined from 23.5 to 13.1% following the recession. There was also a concomitant rise in the

Figure 3 Composition of the foreign-born Mexican population according to years in the United States.

representation of women with more than 10 years of U.S. residence, which rose from 52% before the recession to 64% after 2007. Obviously, since fertility rates tend to be higher soon after U.S. arrival, this change in the composition of the immigrant population has had a dramatic effect on overall fertility rates. It is this change in composition, and not changing family orientations, that explains the lion's share of the drop in immigrant fertility; decomposing the change shows that if the composition of the immigrant flow had not changed in conjunction with the recession, the fertility rate of immigrants would have been only 4% lower in 2010 than in 2006. Again, this estimate is in line with the decline observed among nonimmigrants. Since the overall change was 12%, changing immigrant composition explains more than twice the change in rates than changing behavior.

Conclusions and Implications

In this article, we elaborate on the relation between immigration and fertility, linking two processes that have traditionally been treated as independent population domains in most accounts. The analysis elaborates on alternative fertility measures specifically designed to study immigrant populations that more precisely describe both the level and life-course pattern of immigrant fertility. As applied to the U.S. case, we show that the fertility of immigrants at destination is affected by two time dimensions, age at arrival and time in the U.S. We document that since the timing of migration tends to coincide with family formation, the fertility of immigrants tend to occur shortly after arrival irrespective of age at migration. Failure to account for this association produces much higher estimates of immigrant fertility levels than what are obtained from measures of completed family size.

In addition, we highlight that as a group, immigrants can experience childbearing either at origin, destination, or both. The childbearing contribution of immigrants thus is different whether one considers all children or children only born at destination. For the population dynamics of receiving countries, children born abroad contribute to population growth through immigration; children born at destination more precisely constitute the fertility-specific contribution of immigrants to population growth. The distinction is not generally recognized. Separating the two processes not only presents a different description of the fertility levels of immigrants, but also highlights that their fertility-specific contribution is a lot lower than usually assumed, reducing estimates of how much immigrant fertility can contribute to population growth. We also document that the timing disruption is evident across national origin groups, which makes more of an immigrant than a racial or ethnic trait. The impact on fertility estimates varies by group depending on size, recency, and migration dynamics of immigration.

Two main implications are worth highlighting. The first one is that immigrants should arguably be treated separately from the native born population in demographic analysis. The growing representation of the foreign-born in rich economies implies that the growth and structure of immigrant receiving countries is increasingly affected by immigration. Standard demographic techniques, in our case fertility measures, should not uncritically be extended to immigrants. An initial step in recognizing their differential contribution is to treat them separately in demographic accounts, official reports, and population projections.

The second one is that to the extent that immigration and fertility are related, currently observed fertility patterns are affected by immigration dynamics. When immigration patterns change, then fertility will also be affected. We document this expectation for the U.S. case showing that the decline in immigration explains the larger portion of declining fertility rates after the recession. The connection is particularly relevant for population projections and policy discussions. Accounts of population growth and their age structure into the future should incorporate the notion that variable immigration rates imply variation in fertility rates. In policy discussion, the stand toward promoting or restricting immigration should also take into consideration its effect on fertility.

Migration and Health

Sunshine Rote and Kyriakos Markides, The University of Texas Medical Branch at Galveston, Galveston, TX, USA

Abstract

Most migration takes place within countries, but the number of international migrants, typically from less developed to more developed countries has been on the rise in recent decades. The impact of migration on health is a complex phenomenon. There are health issues associated with the point of origin, point of destination, the journey itself, and return migration. Most research has focused on the health of voluntary immigrants to Western societies and, despite increasing evidence that immigrants are relatively healthy, has often emphasized their health problems rather than any health advantages they may have. Below, the authors review research on migration and health paying particular attention to the health of immigrants at different stages in the migratory process.

Historical Development of the Field

Demographers and social scientists have always been interested in migration, one of the demographic processes which, along with fertility and mortality, determine population size, composition, and distribution (Poston and Bouvier, 2010). Interest in the impact of migration on health has increased over the latter part of the twentieth century. Although most migration in the world takes place within countries, there has been little interest in its impact on health primarily because it is not typically as disruptive as international migration. Previously, most health research was conducted in Western societies where the focus was on the health status and health care needs of native populations. Immigrants were either excluded or were too few, both in number and as a proportion of study samples, to yield reliable estimates of their health status and health needs.

Because the late twentieth century and early twenty-first century have seen increasing immigration to Western societies from poorer nations, scholars and policy makers have made a concerted effort to understand the health status and health care needs of rising numbers of immigrants and how they impact host countries' health and social service systems (Eschbach et al, 1999; Friis et al., 1998; Markides and Gerst, 2011). While attention has focused on the health status of immigrants as a whole, limited attention has been paid to health throughout the migratory process. There has also been some interest in the negative impact of dislocation and forced migration as well as the impact of smuggling and trafficking of migrants. To frame the discussion of research on migration and health, the authors use a migratory process framework proposed by Zimmerman et al. (2011), which includes predeparture, travel, destination, and return.

Predeparture

A number of studies have suggested that immigrants to Western societies appear to be as healthy as if not healthier than native populations. In terms of predeparture, younger and healthier individuals likely select into the migration process. Most people immigrate for employment or occupational reasons, which requires a relatively good level of health. Western countries typically require medical screenings by prospective immigrants. More recently, the Netherlands and Germany have instated predeparture language screenings for migrants from certain developing countries seeking family reunification (Groenendijk, 2011). Additionally, people who immigrate tend to have a positive outlook on their lives and futures, which is consistent with good health (Markides and Gerst, 2011).

Markides and Coreil (1986) suggested such a 'healthy migrant' or 'migration selection' effect to explain the relatively low mortality rates and good health of Mexican Americans living in the southwestern United States. The term 'epidemiologic paradox' was applied because Mexican Americans shared similar socioeconomic characteristics and conditions as African-Americans, yet their mortality and health conditions were similar to the more advantaged non-Hispanic whites (see also, Markides and Eschbach, 2005, 2011).

Research has demonstrated that foreign-born persons are generally healthier than native-born Americans from all major ethnic origins on a variety of health outcomes including mortality risk, functional limitations, chronic conditions such as heart disease, and certain types of cancer (Cho et al., 2004; Markides and Eschbach, 2005; Rogers et al., 2000; Ronellenfitsch et al., 2006; Singh and Hiatt, 2006). In terms of mental health, while most research finds that immigrants have better or similar emotional health as native-born persons (e.g., Dey and Lucas, 2006; Grant et al., 2004), some research reports more psychological distress among immigrants (e.g., Alegria et al., 2007; Angel et al., 2001).

Travel

Most research on the transit phase of migration focuses on the spread of communicable diseases such as tuberculosis and human immunodeficiency virus (HIV)/acquired immunodeficiency syndrome (AIDS), and although most immigrants have no health problems associated with the travel portion of the migratory process, certain groups such as refugees and smuggled immigrants may experience health problems during this phase. The rise of tuberculosis is a major public health concern worldwide. This is especially evident in Western countries, where its prevalence is higher among immigrant groups, especially those from poor countries. Overall, the patterns of the disease among immigrants largely reflect patterns of disease

in their country of origin and are most prevalent among those with living in poverty. Although the overall impact of tuberculosis on the host countries does not appear to be major, it has a major impact among the immigrant communities, especially when immigrants live in crowded and unsanitary environments, conditions that may promote the spread of communicable diseases (Carballo et al., 1998; Spallek et al., 2010).

Research also indicates that the prevalence of HIV/AIDS is less pronounced among immigrant groups (Prossner et al., 2012), but that the distribution of the disease among immigrants is most evident among those of lower socioeconomic standing. In 2010, the United States lifted the restrictive ban on preventing immigrants with HIV/AIDS from entering the country and no longer requires HIV/AIDS testing as part of immigration medical screenings (CDC, 2011). More recently, public health concern has been paid to the problems of HIV/AIDS stigma and poor access to health care among immigrants (Katz, 2012; Ojikutu et al., 2013).

With rising globalization, the numbers of people wanting to immigrate to more developed countries is on the rise. In addition, there is a growing demand for unskilled workers in developed countries and despite more stringent entry requirements, a rapidly growing number of people become victims of international trafficking. Lacking social and legal protection, they often become victims of violence. Pretravel traumatic events like kidnapping and sexual violence can result in psychological distress and mental health problems (Gushulak and MacPherson, 2006).

Smuggled persons may also experience trauma, deprivation, violence, or injury during migration (Gushulak and MacPherson, 2006). Mode of transportation or environmental concerns such as extreme heat or cold or journeys in confined spaces can often lead to illness, injury, or even death (Gushulak and MacPherson, 2000). This has been documented at the United States–Mexico border (Guerrette and Clark, 2005) and among immigrants smuggled from China to Canada (Allan and Szafran, 2005).

As with illegally smuggled immigrants, there is a need to better understand and to better treat the mental and physical health problems of refugees. In a recent meta-analysis, Lindert et al. (2009) found that rates of depression and anxiety are twice as high among refugees as among the general US population. These differences are attributed to possible predeparture war and violence, the strain of migrating, and having little choice in the area of relocation.

Few studies have focused on positive aspects of the immigrant experience, and most focus on the health problems of the immigrants and how they impact the host societies' health and social service systems. Although many immigrants do have special health problems that demand attention, as demonstrated above, the focus on their health problems tends to perpetuate stereotypes that often foster anti-immigrant feelings and actions (Junghans, 1998; Markides et al., 2009).

Destination

Upon arrival to the country of destination, most migrants are in relatively good health. This has been documented in Australia, Canada, the United States, and many European countries. Immigrants, especially those from poor countries, may benefit from the improved living conditions and the better health care of their country of destination. The process of migrating, however, has often been considered a major and stressful life event since it entails a dramatic change in living arrangements, employment, and cultural opportunities (Friis et al., 1998; Markides and Gerst, 2011).

As immigrants live in their country of destination longer and become more acculturated and integrated, their physical and mental health status begins to mirror that of their native-born counterparts (Antecol and Bedard, 2006). For example, Singh and Miller (2004) found that recent immigrants to the United States report less disability and chronic diseases than immigrants with longer durations. Ronellenfitsch and Razum (2004) found that immigrants from Eastern Europe to Germany have better health than native-born adults but this health advantage disappeared after 5 years of living in the country. Similar findings for health convergence among immigrant and native-born groups are also found in Canada (Beiser, 2005).

Timing or age at entrance into the United States can also influence general health outcomes and a range of health behaviors. Migration also leads to changes in lifestyle factors such as poor diet, increased alcohol and cigarette use, and reduced physical activity, which can contribute to adverse health outcomes (Friis et al., 1998; Singh et al., 2011). Foreign-born men and women living in the United States are less likely to use tobacco or drink heavily than native-born adults (Lucas et al., 2003). However, a longer stay in the United States is associated with increases in these health behaviors.

Obesity is another concern worldwide and is shaped by duration in a country of destination. In the Netherlands, the percentage of adults overweight and obese is particularly high among immigrant groups from Turkey and Morocco. Similar results are found for South Asian immigrants living in the United Kingdom (Stronks, 2003). Antecol and Bedard (2006) found that immigrants have lower body mass indexes than native-born adults in the United States; however, these differences were not evident among immigrants living in their country of destination for 10–15 years. This higher risk of weight gain and obesity is likely attributable to changes in dietary habits and increase in sedentary activities, availability of food, as well as psychological distress and problems of social integration.

Another issue that has received attention in recent years is encounters with discrimination. Finch et al. (2000) find that Mexican immigrants living in the United States report more discrimination as they become more acculturated to US language and customs. Viruell-Fuentes (2007), similarly, found that second-generation Mexican immigrant women report more discrimination than first-generation immigrants. Safi (2010) found that both first- and second-generation immigrants' experiences with discrimination lead to lower levels of life satisfaction. Korean immigrants in Canada who report being treated unfairly or being refused services in public areas tend to report greater psychological distress than those who do not (Noh et al., 2007). Overall, discrimination more so than acculturation is seen as integral for understanding the development of health and psychological problems among immigrants since it takes into account the context of social structure and rather than individual adaptation (Hunt et al., 2004; Viruell-Fuentes, 2007).

Community-level living conditions may also impact physical and mental health of immigrants more so than of native-born adults. Zunzunegui et al. (2006) found that immigrants in Montreal were more vulnerable to psychological distress and poor self-rated health in high-unemployment communities than were native-born adults. Lorant et al. (2008) find that immigrants in Belgium from Turkey, Morocco, and southern Europe have poorer self-rated health than native-born adults mostly attributable to higher unemployment and lack of public services in their neighborhoods.

Social support and neighborhood cohesion within immigrant communities, however, may buffer the effects of stressors for health outcomes. Social integration and support can take numerous forms. It encompasses the nature and type of social networks as well as the support perceived or received from friends, family, or the community at large. Eschbach et al. (2004) argue that for Mexican Americans living in the southwestern United States, a high-density immigrant area may provide sociocultural resources that protect against health decline.

Health care access and utilization is also another concern when immigrants reach their country of destination. For some, increases in access to high-quality medical care can improve health maintenance; however, economic and linguistic barriers may pose problems for immigrants. Immigrants are less likely to have insurance and a regular source of care than native-born adults in the United States, are less satisfied with their care, and report more discrimination in health care settings (Derose et al., 2009).

Return Migration

For some immigrants, returning to their country of origin is an expected part of the migration process, although decisions to return may be highly dependent on length of stay in both country of destination and country of origin. Return migration may be fueled by the need for family reunification (Dustmann, 2003), increased employment opportunities at home (Reagan and Olsen, 2000), retirement, or even health complications and a desire to die in one's homeland (Abraido-Lanza et al., 1999). For immigrants in the United States who return to Mexico, the process has been described as a 'salmon bias' since these immigrants may die in their country of origin and, therefore, are not taken to account in studies of immigrants and health/mortality in mid or later life. There has been partial support found for a salmon bias, but researchers have found that it is too small to account for the mortality advantage of Hispanic immigrants (Turra and Elo, 2008; also see: Markides and Eschbach, 2011). Similarly, Riosmena et al. (2012) find partial support for a salmon bias but this was most evident among immigrants who had been in the United States for shorter durations.

Conclusions and Future Research

Overall, research indicates that immigrants are in relatively good health upon arrival mostly due to the process of healthy individuals selecting into the process of migration. After living in a country of destination for longer, their health status seems to converge to similar levels as native-born persons. Some explanations for convergence include changes in daily activities, eating habits, and exposure to discrimination. Groups of immigrants such as refugees, illegally smuggled immigrants, and those living in poverty have health concerns associated with the travel and destination phases of the migratory process. Certain groups may return to their country of origin when faced with health complications.

One of the biggest obstacles to studying migration and health is a lack of available survey data. Some time ago, Kasl and Berkman (1983) outlined an ideal study design that would involve migrants-to-be, nonmigrants at the point of origin, and native residents at the point of destination. Following the same individuals across borders and throughout the migratory process and asking about a range of psychosocial and environmental characteristics will lend better insight to the health immigrants bring with them to the process, the social context of their lives in the country of destination, and important areas of intervention to ensure the health of immigrants at every stage of the migratory process.

While such a study would be a massive undertaking, some other considerations for future data collection is to provide more information about the characteristics of the immigrant experience, including the length of stay in the country of destination, health behaviors pre- and postdeparture, and the characteristics of the immigrant experience in different domains: work, family life, and community. There is also concern about the diversity in immigrant populations and how overarching terms of 'Asians' or 'Hispanics' may hide important intraethnic variations in the migration experience and health outcomes. Focusing on specific immigrant groups along with health-related outcomes (access to medical care, obesity, and health behaviors) will lend to a better understanding of the complex and dynamic process of migration's influence on health.

Migration and Social Capital

Nadia Y Flores-Yeffal, Texas Tech University, Lubbock, TX, USA

Abstract

Migration social capital is referred to the tangible and/or intangible benefits acquired by international migrants as a result of having contacts (or social networks) at the place of origin and/or at the place of destination of the migrant. Those benefits can be acquired at any time during the migratory process, such as, during the first migration trip and later trips, while crossing international borders, and during and after the settling process. It reduces the cost and risk associated with international movement. Social capital is often provided by *paisanos* (or countryman), friends, or by family members.

Introduction

Scholars studying international migration theory and the economic sociology of migration tend to address the social, noneconomic reasons for migration such as social networks and social capital. International migration scholars have borrowed the concept of social capital to refer to the benefits (tangible and intangible) acquired by international migrants as a result of having personal contacts with prior migrants at the place of origin or at the place of destination. The information and resources provided help to increase the likelihood of migration by nonmigrants as migration social capital helps to reduce the cost and risks associated with international movement (Massey and Espinosa, 1997). The information and resources provided by migrant social capital can work differently for different people and in different settings (Garip, 2008). In addition, the distance between the place of origin and the place of destination also can make a difference with regards of how migration social capital operates (Massey et al., 2011). In addition, rural or urban places of origin may also dictate how much migration social capital may be available in different settings and how it functions (Fussell and Massey, 2004; Hernandez-León, 2008; Flores-Yeffal and Aysa-Lastra, 2011; Flores-Yeffal, 2013). The context of the place of origin is therefore considered very important as the structure of the social networks in which social capital is exchanged could take many different forms (Flores-Yeffal, 2013).

The contemporary meaning of social capital was first introduced by Loury (1977) and theoretically developed by Bourdieu (1986) and Coleman (1988). Originally, the concept was not necessarily associated with issues of international migration until the term became very popular and international migration scholars began to borrow it in order to explain the role of social networks in the international migration scenario (i.e., Massey et al., 1987). Given that the origins of the concept were not necessarily conceptualized in the realm of international migration, sociologists in general disagree about what constitutes social capital, but international migration researchers generally agree that it refers to the tangible and intangible resources provided by relatives, friends, and *paisanos* (countryman) to facilitate migration, settlement, and employment in a foreign country (see Massey et al., 1987; Massey and Espinosa, 1997; Flores-Yeffal, 2013). Past studies about Europeans demonstrate that historically and around the world in the past international migrants have utilized social capital to migrate. For example, Gans (1962) wrote about European-origin segregated immigrant communities during the turn of the twentieth century in Boston. These communities had developed as a result of social networks and social capital exchange.

Today, the field recognizes mainly two theories related to social networks: *the cumulative causation theory* and *the social capital theory*. Actually, the social capital theory is considered part of the *cumulative causation theory* (see Massey et al., 1998). The theory of cumulative causation refers to the tendency of migration to self-perpetuate, regardless of what initially caused the migration to begin (Myrdal, 1957; Massey, 1990). As more people migrate, more migration social capital accumulates and so more people migrate from a single community as a result that international movement becomes easier and less costly to others. This theory takes into account the changes in context and social culture in the transnational context, at the place of origin, as well as at the place of destination. For example, it claims that a culture of migration develops among the members of the sending community due to the benefits they observe from international migration and remittances. For example, they may see other people in the community receiving remittances from abroad and building new homes, buying new clothes for them and their children and so they think that if they were to also migrate abroad, that they would also be able to provide the same amenities to their family members. This particular reaction is usually referred to *relative deprivation* in the international migration literature (Taylor, 1986). After seeing the benefits at the place of origin, more people decide to migrate internationally for the same reasons. They utilize their contacts and social networks to facilitate their migration.

The social capital theory, on the other hand, has to do with the concept of the benefits provided to prospective migrants having contacts at the place of destination. According to this network theory, migration becomes easier and less costly and risky over time because of a growing network of social contacts in the receiving community. These contacts share information and resources with future migrants, whether family, friends, or people from the same community, aiding in the process of migrating, settling, and searching for employment in the host country. These resources and connections are a form of social capital that dramatically increases the likelihood of additional migration among persons with family or friends living in the

US (Massey et al., 1987; Massey, 1990). Sociologists view such social structures and interpersonal networks as potential sources of social capital.

The Sources of Social Capital and International Migration

Portes and Sensenbrenner (1993) defined social capital as "collective expectations affecting individual economic behavior" (p. 1326). They used classic sociological concepts and introduced four sources of social capital mainly related to international migration based on the collective behavior of people:

1. Value introjections: "socialization into consensually established beliefs" that prompt behavior that is not simply out of naked greed
2. Reciprocity exchanges
3. Bounded solidarity: "situational reactive sentiments", which result in collective conscience
4. Enforceable trust: "pluralistic rewards and sanctions linked to group membership" (Portes and Sensenbrenner, 1993: p. 1326).

Immigration scholars have used such sources of social capital primarily to examine economic enterprises formed by immigrant entrepreneurs. In fact, Portes and Sensenbrenner (1993) expounded the above-mentioned concepts of social capital using examples chiefly related to immigrant ethnic entrepreneurship enterprises, and not solely as examples of social support in order to migrate and settle in the US Studies of social networks among unskilled and undocumented immigrants have neglected to examine closely the sources of social capital formulated by Portes and Sensenbrenner, due to the generalization that undocumented immigrants do not tend to form economic enterprises (see Valdez, 2011). The concept of Migration-Trust Networks developed by Flores-Yeffal (2013) provides an avenue for further developing the sources of social capital proposed by Portes and Sensenbrenner (1993), especially reciprocity, bounded solidarity, and enforceable trust relevant to the help provided to international migrants who lack legal documentation to migrate. Migration-Trust Networks refers to the social network of people in which the majority of its members lack legal documentation. Migration-Trust Networks she argues are mostly driven by relationships of trust and the social monitoring of its members. Its members tend to segregate themselves at places of destination in order to provide information, resources, and social support to the rest of the members of the group who also lack legal documentation.

Portes and Sensenbrenner (1993) proposed the concept of *bounded solidarity* as a source of social capital, which "focuses on those situational circumstances that can lead to the emergence of principled group-oriented behavior quite apart from any early value introjections" (p. 1324). In other words, the members of the group develop certain expectations of collective behavior in which any actions or decisions made should benefit not just the individual but all the members of the group. Portes and Sensenbrenner (1993) argue that one example of the situational circumstances immigrants face that lead to such bounded solidarity behavior is the extent to which they are subject to racial or ethnic discrimination once they arrive to the US.

Supportive behavior happens under certain social circumstances according to some sociologists. For example, the mechanical solidarity concept by Durkheim (1997[1933]) in which he argues that in small (rural communities) people tend to like each other because they have similar occupations and skills with each other, and feel collective conscience to each other (don't think of themselves as individuals, but as a group), and the members of the community enforce a series of values and norms between each other which leads to cooperation among the members of the group. Similar to the Mechanical Solidarity concept, the idea of *enforceable trust*, proposed by Portes and Sensenbrenner (1993), refers to a set of social expectations to follow that will be enforced through social monitoring, which can result in the rejection or punishment of those who do not conform to those agreed-upon values and behaviors. The similarity of experiences, such as crossing the border clandestinely, feeling discriminated against, sharing the fear of being caught by the border patrol, and being exploited in the US, gives rise to the enforceable trust social mechanism among migrants once they identify each other in the US. Also, Tilly (2007) has argued that international migrants help each other through bounded solidarity due to a series of expectations from the members of the rest of their group and that the social networks of migration from transnational communities are based on trust networks. Flores-Yeffal (2013) also argues that the social expectations of behavior at the community of origin are transferred to the place of destination and that the transnational relations of trust among migrants and nonmigrants create the fundamental conditions for the exchange of social capital among network members, more specifically to what she calls, Migration-Trust Networks.

Religion also plays a major role in the exchange of social capital as migrants in many cases help others and support others out of religious faith thinking that by helping others, they will probably be rewarded by God and, therefore, they will do better in the future (Hagan, 2008; Flores-Yeffal, 2013). This religious faith is often embedded within their culture and such culture is also preserved when international migrants travel and settle at the places of destination.

Portes and Sensenbrenner (1993) took into account that reciprocity was an important source of social capital and assumed it was directly by the exchange of favors amongst immigrants; this is to say, those who received favors later returned them to the givers. Instead, Flores-Yeffal (2013) found evidence that in the case of Migration-Trust Networks, in which most members of the network lack legal documents, the members of the network do not necessarily return the favor directly to the person who originally provided the help, instead, international migrants tend to pay the favors forward to other future migrants. This happens because those who provide the help are usually more established migrants than the newcomers. She refers to this type of social exchange as, "risk pooling" (Flores-Yeffal, 2013). Therefore, reciprocity relations may vary depending on the group dynamics during social capital exchange.

In the field of international migration and social networks, experts have claimed that networks are not necessarily static entities, but that they change and transform over time (Boyd,

1989; Granovetter, 1985; Hagan, 1998; Mahler, 1995; Menjívar, 2000). For example, Boyd (1989) found that those who participate in social networks meet specific roles and functions such as those networks used to just get to the US as a first-time migrant, while others participate in networks which are used later once the migrant is more established. In addition, studies of social networks among migrants have found that competition among immigrants or exploitation of fellow countrymen may disintegrate ethnic solidarity and cohesiveness among network participants (i.e., Mahler, 1995; Menjívar, 2000).

Type of Social Ties That Provide Social Capital to International Migrants

Mark Granovetter (1973) revolutionized the organizational literature when he presented the concept of "The Strength of Weak Ties". Granovetter (1973) argued that weak ties could get people better jobs, as the information obtained by acquaintances was of a better quality and more efficient than that obtained by more established network ties, or from strong ties. He argued that the information obtained by strong ties was usually more redundant, less effective, and inefficient. Later on, Granovetter revisited his theory and acknowledged that strong ties were also effective for people during times of risk and uncertainty (Granovetter, 1982, 1985). Scholars in the area of international migration have debated as they have found that strong ties have been also effective for international migrants in getting better jobs and/or better wages (Mouw, 2003; Aguilera and Massey, 2003). Later on, Flores-Yeffal also concluded that indeed, international migrants often began using what many called, weak ties for obtaining social capital from *paisanos*, but that later on those ties were transformed on strong ties and became more effective for social capital exchange through the Migration-Trust Networks in the case of Mexican undocumented emigration to the US (Flores-Yeffal, 2013).

Social capital is usually exchanged by family members, friends, or *paisanos* (or countryman). According to Flores-Yeffal (2013), *paisanos* play a crucial role in the exchange of social capital given their important role as pioneers as they are usually the first ones to migrate internationally. At first, not everyone has a family member abroad and for that reason it is more difficult for family members to be the ones providing help to newcomers. It is not until a lot of people from the same community have migrated internationally that more family members will be available to provide the help (see Flores-Yeffal and Aysa-Lastra, 2011).

Certain ethnic behaviors among the members of specific groups (among Mexican migrants, for example) tend to develop fictitious ties in the absence of other ties to exchange social capital. Among Mexicans migrants, for example, one very important way in which both rural- or urban-origin international migrants increase their chances of receiving social support or social capital at the time of migration is through the use of fictitious ties. *Cuatismo* is a type of fictitious tie practiced with the purpose of strengthening social relationships, especially among males. *Cuatismo* is a form of friendship, but stronger (Lomnitz, 1977). *Cuates* usually get together more often than normal friends, share intimate information, and support each other more strongly. Migrants who are *cuates* get together on Sundays, for example, to watch soccer games and drink beer, plan vacation trips together, spend holiday celebrations together, and also become *compadres* in order to further strengthen their relationship (Flores-Yeffal, 2013).

Studies have found that in Mexico and other parts of Latin America, *compadrazgo* is a way to build stronger relationships of trust, or to convert a weak relationship into a strong relationship in which participants grow closer (Lomnitz, 1977; Flores-Yeffal, 2013). Becoming a compadre can mean even more than being a cuate; it is a stronger relationship and more focused on family. One way to become a person's *compadre* or *comadre* is to baptize his or her child, thereby assuming responsibility for the child if something were to happen to the parents. This demonstrates trust and care, which in turn, strengthens their existing relationship and upgrades it to something similar to a kinship tie, or even stronger in certain cases.

Compadres and *comadres* tend to interact with each other with more frequency and spend more time together than with their own family members. Through *compadrazgo*, even those who have never met before can transform their social relationship into a strong relationship of trust and loyalty into the future. Migrants benefit from those types of fictitious ties because more social support and social capital becomes available to them. *Compadres* and *cuates* would provide social capital to international migrants in many cases in the same way a family member would do.

First Trips vs Later Trips

Migration social capital is usually more available to first-time migrants than to returning migrants, given the auspices associated with making a first trip (Massey and Espinosa, 1997; Flores-Yeffal and Aysa-Lastra, 2011). Most first-time migrants need some sort of information and assistance regardless of their legal status at the place of destination. The most important social capital they need is information on where to go, what to say, what to bring, how to find a job, where to live, how the system works, and so forth. Someone has to provide them with such information for their trip to be successful, otherwise, they may end up going through a lot of trouble, getting to a place in which they cannot find housing or jobs, and end up having a not-so-good experience. Social ties usually tell prospective migrants in advance whether there are jobs available or not at the place of destination, so most first-time migrants already know whether they will be able to find jobs or not. García (2005), for example, argues that once international migrants get to the place of destination, they already have jobs waiting for them. Usually, employers tend to notice the good working ethic of the workers of that specific network and then use those workers to recruit more workers who would probably also have good work ethic (García, 2005). The monitoring behavior of the people who belong to the network makes sure that those who are recommended for new jobs are responsible on their jobs, so more people in the network can have access to jobs in the future (García, 2005).

Those who lack legal documents to migrate besides information of where to go and what to do to find a job also need crucial information on how to be safe and avoid getting caught by immigration authorities or be deported. For this reason,

first-time migrants need crucial information, for example, on how to get to the border, where to find a Coyote (or smuggler), where to go once they are at the place of destination, and how to find a job without having legal documents. According to Flores-Yeffal (2013), Migration-Trust Networks provide such information to undocumented immigrants and they also provide a place to stay, food, clothes to wear (as they usually arrive with the clothes they are wearing), transportation, help to find a job without having legal documentation, where to go to the doctor, and help to get settled.

Returning migrants usually build human capital during each trip (see Massey and Espinosa, 1997), so they learn from their prior experiences and then they tend to rely on social capital less and less. The problem is when the rules change and the receiving country changes immigration laws and strengthens border control, for example. If the migrant knew how to cross the border before without hiring a smuggler, for example, once the rules change, the way the migrant knows how to cross, may become too risky again, so he or she would need information on how to find a trustful smuggler or Coyote. The information provided to first-time and returning migrants has to be trustful because their lives would be at risk if something goes wrong (see Flores-Yeffal, 2013). Some smugglers utilize very risky ways to transport migrants and cross them through the checking points, such as to put them inside trailers in crowded conditions and without air conditioning and in many cases the migrants can suffocate, for example.

According to Flores-Yeffal (2013) undocumented immigrants from Mexico experience the following step-by-step process to access social capital from others.

International Migration Begins

First, pioneer migrants leave their community and settle in the US. Many belong to pre-existing clique-like networks or peer groups and begin to invite their pre-existing ties to also join the migration journey. Family members are less available to provide help, so instead friends and *paisanos* – especially *paisanos* – offer prospective migrants the social capital to migrate.

Activation of Migration-Trust Network

For some communities, only a small number of pioneers are required to migrate internationally for the Migration-Trust Networks to be activated. Once migration begins, then subsequent migration occurs, and therefore, more people migrate from that community. The demands for cheap labor at the place of destination also helps to increase the migration flow. The context of reception then also becomes important for the flow to continue to grow. The context of reception is referred as the resources available to new arrivals at the place of destination, such as housing, jobs, transportation, food supply, schools for the children, and medical facilities. The prevalence of such amenities provides additional incentives for the migration flow to continue to grow.

Formation of Immigrant Enclaves

In search of social support and the exchange of social capital, recently arriving pioneer migrants begin to live next door to one other upon arrival. Such living arrangements allow for access of social support from others, easier enforcement of norms, and social monitoring among MTN members.

Pre-Existing Relationships of Trust

Prior relationships of trust are essential for the Migration-Trust Networks to function properly at the place of destination and in the transnational context. Such pre-existing conditions of social trust and social cohesiveness are necessary to effectively provide social capital to more newcomers and prospective migrants.

Relations of Trust

The vulnerability of undocumented migrants, for example, can only be overcome through reliance on relationships of trust. If a relationship of trust does not exist before migration, then a new relationship of trust may develop at the destination through religious ties and/or the commonalities related to the international migration experience and struggles back home.

Nonreciprocal Exchange of Favors

Favors are not necessarily returned to those who originally assisted migrants. Instead, favors are passed along to the new arrivals or returning migrants, which contributes to the growth of the Migration-Trust Network. While they may help from purely altruistic reasons, migrants do gain social status by helping others.

Sanctioning

Members of a migrant network are socially monitored by the other members of their network. Social capital exchange is one of the social expectations of migrant networks as people are expected to help others to migrate. Those who do not meet the social expectations of behavior and norms may be rejected or punished. Social monitoring not only occurs at the place of destination, but also at the place of origin of the migrants. People are monitored via several forms of technology, such as telephone, cellphones, videos, YouTube, and social media web sites. People posts pictures and show their behavior to others no matter where people are and those who have access are able to monitor the behavior of others.

Transnational Networks

Expansion of Migration-Trust Networks depends on transnational relations between migrants and those left in the sending community as they exchange social capital and vital information. They maintain transnational relations (between the place of origin and the place of destination of the migrant) largely through technology, such as cell phone communication, community Internet web sites and blogs, the use of Skype or Facebook, letters, videos or YouTube videos, movies, and pictures. Through such transnational contact, cultural ideas and practices are exchanged. Migrants are encouraged to carry and maintain their cultural practices at the destination, and they introduce aspects of the host culture to their home communities (Fitzgerald, 2008; Smith, 2006).

Conclusion

Therefore, migration social capital results from having contacts with prior migratory experience. Those migrants understand the hardship and dangers associated with the international migration experience and they are willing to provide first-time migrants and returning migrants with all the information and help necessary for them to migrate to the place of destination and get established. First-time migrants receive in general greater amounts of social capital and undocumented migrants tend to relay on Migration-Trust Networks as they confront greater risks.

Several social factors can influence how social capital is exchanged. The list goes on and on, but some of the factors discussed here are the history of migration of the particular flow, the context of the place of origin (whether rural or urban), legal documentation of the migrants, religion, culture, social values, the conditions of the context of reception, transnational politics and transnational relations between the place of origin and the place of destination, the type of social ties available, the age of the migration flow, the distance between the place of origin and the place of destination, the social and immigration policies in place at the place of destination, and so forth. In order to understand how social capital is exchanged within a particular international migration flow, several factors would have to be taken into account before one can understand its structure and how it functions.

Migration and Social Work

Usha George, Ryerson University, Toronto, ON, Canada

Abstract

This article highlights some of the key issues related to social work with migrants. It describes international trends in migration and provides an overview of migrants' needs and challenges. The article details the types of interventions, social workers provide to migrants and discusses some of the key issues facing the profession in terms of its interventions with migrant communities.

Introduction

Migrants broadly include four categories of persons: immigrants, refugees, temporary residents, and 'illegal' or undocumented immigrants. Immigrants are persons who choose voluntarily to migrate from their country of origin to another to take up permanent or temporary residence. Refugees are persons who are outside their countries of origin and forced to seek protection in another country on account of war, natural disasters, or of fear of being persecuted on account of race/ethnicity, nationality, or membership to a particular group. Temporary residents include visitors, students, seasonal workers, and persons who are allowed to live in a host country for a fixed period of time. 'Illegal' or undocumented immigrants are persons who enter a country without valid documentation or continue to stay on after the expiry of their visas. Each category of migrants has to overcome unique sets of challenges in their immigration and settlement in the political, social, and cultural context of their host countries. As a helping profession, social work assists individuals in responding to these challenges.

Further classifications of each migrant type might exist within countries. For example, in Canada a distinction is made between 'skilled' or 'economic immigrants' who qualify for immigration on the basis of 'points' they earn on a set of criteria in relation to their skills and qualifications, and 'family class immigrants' (the spouses/common-law partners, dependent children, or parents sponsored by permanent residents or citizens). In the United States of America, migrants could be permanent residents (green card holders), permanent or temporary workers, refugee or asylum seekers, while in Australia, migrant categories include employer and state/territory government sponsored migration, family sponsorship, and options for highly skilled business owners, investors and senior executives options.

The most prevalent 'push–pull' theory of migration (Lee, 1996) suggests that migrants might either be 'pushed' out of their country of origin due to conditions such as persecution, natural calamities, and lack of opportunity, or they might be 'pulled' by attractive features of their host country such as better employment opportunities and/or a better political/social climate. A version of this theory suggests that migration is a result of factors at the macro- or structural level (such as international socioeconomic political forces); at the meso-level (relationships between potential migrants in host countries and country of origin); and micro-level (individual factors) (Potocky-Tripodi, 2002). According to this theory, economic globalization brings with it an increased concentration of wealth in industrialized nations and stagnant economies in regions characterized by poor employment prospects and little or no state provision for social security. It is suggested that mass migration is a product of globalization's inability to create employment in countries of high need (Li, 2003).

Key Trends in International Migration

Most countries in the Northern Hemisphere have formal and informal mechanisms in place to either increase, decrease, or maintain migration, with a goal of population growth/maintenance and/or labor management. In the year 2009, Denmark, France, the Netherlands, and Russia aimed to reduce immigration while Australia, Canada, Estonia, Finland, New Zealand, and Sweden aimed for increased skilled labor immigration (Rajan, 2012).

Some of the more salient trends in international migration are the increasing number of international migrants, global movement of refugees, decreasing number of asylum applications, the feminization of migration (Castles 2000 in George 2007), and an increased demographic diversity in the host countries due to migrant flows from nontraditional source countries. International migration is highly interrelated to globalization, and associated developments such as improved transportation, communication, and growing international trade (Suárez-Orozco and Qin-Hilliard, 2004). Political changes in Middle East and North Africa, natural disasters in China, Pakistan, and other regions in Asia and a global economic crisis have all contributed to increased human migration worldwide in the past few years (IOM, 2011). In 2010, the total number of international migrants was 214 million people, 23 million more than what it was in 2005 (IOM). Among the Organization for Economic Cooperation and Development member countries, the United States of America continues to have the highest inflow of foreign migrants. Other countries with high inflows of foreign migrants were Australia, Germany, Canada, United Kingdom, Italy, and Spain (OECD, 2012). The numbers of refugees of concern to United Nations High Commissioner for Refugees were 10.5 million at the beginning of 2011. An additional 4.8 million registered refugees were being looked after in

refugee camps in the Middle East (UNHCR, n.d.). Developing countries were hosts to the largest number of refugees worldwide in 2011, with Pakistan hosting the largest number of refugees followed by the Islamic Republic of Iran (UNHCR, 2011). In 2011, the United States also saw the highest inflow of asylum seekers, followed by France and Germany (OECD).

Feminization of migration refers to the trend where almost half the world migrants in recent times are women, with an increasing number of women migrating internationally for work, apart from the more traditional reasons such as reunification with family. A gendered analysis of migration helps to understand the manner in which gender inequalities constitute the reason or become the consequences of migration, as well as the impact of women's migration on the families in the countries of origin (Morrison et al., 2008). Women constituted 49% of the world migrants in 2010, with an overrepresentation of women in the age groups of 65 and over (United Nations, 2010). Globally, migrants tend to be of working age, with the average of international migrants in 2010 being 39 years. Migrants to developed countries tend to be older than those to developing countries (United Nations).

Needs and Challenges Faced by Migrants

Needs and challenges faced by migrants are interrelated. However, this section will present needs as those necessities that the migrants must be able to meet in order to make the successful transition in their host countries. Challenges refer to those societal-level barriers faced by migrants in trying to meet their needs.

Migrant Needs

- *Information and Orientation*: Literature has demonstrated the primacy of the need of information and orientation for new migrants (Valtonen, 2008; Segal, 2002). Migrants need information related to almost all aspects of living and adjusting to their host society such as cultural norms regarding appropriateness of behavior, dealing with formal institutions, and how to access services. In practice, many migrants pursue informal channels of information and orientation over more formal sources.
- *Language Training*: Language barriers impact not only job opportunities but also opportunities for everyday interaction, socialization, learning, and integration. While language ability is one of the selection criteria for principal applicants, the dependents of principal applicants and other categories of migrants such as refugees are not subject to language proficiency requirements. The inability to speak the dominant language of the host country places migrants at a disadvantage in the labor market (Kler, 2006; Dustmann and Fabbri, 2003).
- *Employment*: Adequate income is a prerequisite to meet the needs of a family. Economic migrants, who have migrated on the merit of past educational and professional experiences, look for work that is commensurate with their credentials. However, migrants are often unable to secure work in their areas of expertise due to the nonrecognition of credentials by professional bodies and are required to requalify through education and/or internships. The inability of migrants to find appropriate employment has been found to be associated with lower self-esteem, anxiety, and a sense of hopelessness (Cabral, 2000), as well as dissatisfaction with life in the host country.
- *Housing*: As housing is dependent on income and employment, migrants are often forced to live in conditions of housing instability (Ballay and Bulthuis, 2004). In the case of economic migrants, the lack of adequate income results in substandard housing, inferior to what they were used to in their own countries of origin. Availability of affordable housing suitable for a family's needs is always a challenge. Access to public transport, schools, and hospitals is a major factor determining the choice of residence for a majority of migrants.
- *Networks and Social Support*: All migrants leave behind networks of family and friends to start life anew in their host country. In the case of refugees, this separation might have been involuntary or even violent and traumatic. In creating new social capital, the preexisting and self-created supportive networks are very important to migrants as sources of information and orientation and in looking for and finding employment (George and Chaze, 2009). Creating new social supports is a slow process and contingent on many other factors such as language ability, income, and transportation, and the existence of ethnic and cultural networks. For migrant women experiencing violence within the family, many factors such as language barriers, race, migrant status, loss of traditional sources of support due to migration, and lack of faith in formal sources of support intersect to heighten their vulnerability to victimization (Menjívar and Salcido, 2002).
- *Mental Health*: There has been an acknowledgment of the unique mental health needs of refugees in coping with their past trauma. Apart from loss of networks, most migrants experience downward social and economic mobility at least in the initial years as they go through the process of settlement in their host countries. Migrants in an alien context and culture have to deal with challenges to their core assumptions about the world, 'culture shock,' along with a loss of familiar cultural environments including language and belief systems (Berger and Weiss, 2002: p. 24). The separation, losses, disruptions, and stressors affecting migrant's lives due to the migration process have been conceptualized as trauma (Berger and Weiss, 2002). Social discrimination, economic deprivation, and lack of networks are linked in turn to the incidences of alcohol and substance abuse (Balgopal, 2000). There is an increasing recognition of migration experiences as a determinant of health.
- *Family Relationships*: The bicultural identity conflicts faced by migrants (Segal, 2002) as well as their children (IFSW, 2012) and the tensions that arise in the family due to the value conflicts in multigenerational households can lead to escalated stress and tension. Differences in the migrants' child-rearing practices, including disciplining (Balgopal, 2000; Segal, 2002) and those of the host society are likely to increase stress. Senior immigrants might be dependent on their adult children for a range of support and needs. The loss of traditional networks and ways of living increases their vulnerability to abuse within the family (Potocky-Tripodi, 2002). Marital relationships become

impacted by the changed gender roles, increased demand on women's caring responsibilities, difficulties in balancing provisioning and labor market activities, and isolation (Potocky-Tripodi, 2002; Menjívar and Salcido, 2002).

Challenges

- *Conceptions of Citizenship*: The notion of citizenship includes dimensions of legal status, rights, participation, and belonging (Bloemraad et al., 2008). Countries differ in their visions of who can become a citizen and whether equal citizenship can be conferred upon persons who are ethnically different from the majority host groups; and whether this citizenship is granted at birth (*jus soli*) or granted to the individual on the basis of their parents' citizenship status in the country (*jus sanguinis*). Notions of citizenship also differ in terms of whether the goal of citizenship is furthered better through policies focused on multiculturalism and group rights, or in contexts that promote the shedding of group/community based affiliations toward assimilation into one national identity (Bloemraad et al., 2008). The host country's conceptions of citizenship, whether assimilationism or multiculturalism has a bearing on the reception and accommodations the migrants receive in the host country and their subsequent integration.

The category and class of migration has the potential to determine not only the specific challenges migrants face in their host countries, but also the country's response to the needs of the migrants. Among the migrant categories, refugees are particularly vulnerable in that not only do they come from regions that are linguistically, culturally, and politically very different from their host society, they also have to deal with traumatic preimmigration experiences. Most countries actively disentitle refugees. In the United States, for example, undocumented migrants are ineligible for all federal public assistance programs with the exception of emergency health care and schooling for children (Park and Bhuyan, 2011). Women and other dependents those migrate on conditional residency requirements are particularly vulnerable to abuse at the hands of the sponsor. Seasonal workers have also been identified as a vulnerable migrant category as they are in danger of being exploited in their employments and are often not eligible for the protection and other services available to permanent migrants.

- *Integration Policies*: Countries show great diversity in terms of the policies and programs they have in place for integration of their migrants. These range from those that lean toward assimilation at one end (e.g., Unites States of America) and toward pluralism or multiculturalism at the other (e.g., Canada) (George, 2006; Valtonen, 2008). The host country's policy toward immigrant integration is a very important factor impacting the migrant's adjustment, which can be measured along on a continuum – from acculturation and assimilation at one end to rejection of the culture at the other (Segal, 2002). Countries like Canada, Australia, and New Zealand, for example, have immigration laws in place that allow foreign nationals to apply to enter the country as permanent residents. In the United States, immigration policy is largely concerned only with the management and policing of the entry of migrants into the country and services targeted specifically at integration are available only to refugees (Potocky-Tripodi, 2002). Canada and Israel, among other countries, have numerous services to facilitate the settlement and integration of newcomers. Host countries tend to have different arrangements for who pays the bill for the services available to newcomers – the government or the newcomers themselves.
- *Institutional Readiness*: The settlement and integration of migrants into the host country depends to a large extent on the country's institutional structures – preexisting relationships between races and ethnicities within the population; the labor market and related institutions; government policies that either directly or indirectly impact upon migrants and the place of the host society within the globalized economy (Reitz, 2002) – and reflects "the host society's belief of the place of foreigners in their midst, and more broadly the role of government in civil society" (Siemiatycki and Triadafilopoulos, 2010: p. 21).

Migrants often face difficulties in achieving good economic outcomes in their host countries (OECD, 2013; Buzdugan and Halli, 2009) and often work in jobs that require lower levels of skills (IMO, 2012; Stier and Levenon, 2003). Economic migrants may face challenges in relation to language skills and securing employment that recognizes their past education and work experiences (Valtonen, 2001; Tiiseto, 2011). Requirements related to local work experience, and referrals in the context of limited social networks reduce their access to appropriate employment. Other categories of migrants may have restrictions on working in the host country. Temporary or seasonal migrants may be constrained by conditional work-stay requirements, increasing their vulnerability to exploitation (Amnesty International, 2012).

Another area that exemplifies the importance of institutional readiness within host societies is housing. In Canada, for example, migrants often face difficulties in accessing adequate housing (Teixeira, 2008) and are increasingly represented among the category of absolute homeless, while refugees in particular are among the worst affected groups (Ballay and Bulthuis, 2004). Other barriers that migrants face when attempting to secure housing have been identified as administrative requirements such as having a cosigner as a guarantor; knowledge of neighborhoods and housing systems, lack of skills in conducting a housing search and skills in negotiating with landlords, language and accent barriers, and social housing waiting lists (Hulchanski, 1997).

- *Xenophobia*: Migrants all over the world often face hostility from the native born population in varying degrees and with different consequences (Bunar, 2007; Hale et al., 2011; Henry and Tator, 2005). Migrants are frequently viewed as a threat to the material security and cultural integrity of host society, a sentiment that is often capitalized or even promoted by some right wing- or xenophobic politicians (Mughan and Paxton, 2006; Bunar, 2007). This hostility gets amplified in bad economic times where migrants might be seen as competition for scarce employment opportunities (Mughan and Paxton, 2006). In most countries, the hostility is covert, and displayed through everyday discriminatory acts of limiting the migrants' access to the

equal opportunities enjoyed by the majority of the population (Segal, 2002), often resulting in institutionalized exclusionary practices (Henry and Tator, 2005). In other countries, the hostility toward migrants may be much more pronounced and displayed through intergroup conflicts and violence including hate crimes ranging from verbal abuse to murders (Bunar, 2007; Hale et al., 2011).

- *Underutilization of Services*: The underutilization of service, and health and mental health services, in particular, is a recurring theme in the migration literature (George, 2007; Guruge et al., 2009). There are many reasons why migrants may underutilize services: there may be language and financial (real or perceived) or cultural barriers to accessing services; migrants might lack knowledge of services available and/or their rights to access these. Also, they may not be eligible to access the services based on government policies of their country; and/or there may be fear of disclosure of status accompanying access of services (Murray and Skull, 2005).

Social Work with Migrants

Social workers have a long history of involvement with immigrants and refugees. The foundation of social work is synonymous with the Settlement Houses created in the early and late nineteenth century primarily to serve and help immigrants and relocated persons, first in London in Toynbee Hall and later replicated in the United States by Jane Addams (Brieland, 1990). Social work with migrants has been historically geared toward helping newcomers adjust to their new societies with the aim of enabling them to become 'good citizens' (Balgopal, 2000). In recent years, this focus has become more migrant-centric, with an acknowledgment within the profession of emphasizing the importance of the successful adjustment of the migrant and on the removal of barriers to their participation in the host society (IFSW, 2012).

The demographic profile of migrants has changed significantly over the past decades and social workers now increasingly have to work with persons from very different cultural and ethnic backgrounds. Social work responded to these challenges in the 1970s and 1980s with a call for appropriate interventions, both at the individual and structural levels (Tsang and George, 1998). This included antiracist (Dominelli, 2002; George, 2000) and/or antioppressive approaches (Dominelli, 2002) that emphasize the structural origins of problems (Mullaly, 1997).

Social work intervention with migrants generally occurs through settlement service work with new migrants. These services are targeted at migrants to assist them in meeting the most direct immediate needs of settlement in the host society. Social workers employed in the migrant settlement field are generally involved in providing two kinds of services to migrants. *Direct services* including information and referral related to settlement needs, as well as counseling. For refugees, apart from providing information, social workers have a role to play in mitigating the intensity of trauma experienced through appropriate humanitarian service response (Drumm et al., 2003).

Indirect services include advocacy, planning, and coordination with other organizations to increase service efficiency (Potocky-Tripodi, 2002; IFSW, 2012). As advocates, social workers have to educate the public and government about the needs and challenges faced by migrants as well as the resource needed to address these issues. Social workers have to be aware of immigration policy changes and the manner in which these shifts affect practice (Park and Bhuyan, 2011). An important role that social workers have in the context of *advocacy* is to ensure that migrants have opportunities for equal citizenship (in the broadest sense) in their host country. In a multicultural society, these include access to equal opportunities, the elimination of discrimination, opportunities to practice and transmit culture, and the public acceptance of migrants as legitimate members of society (Valtonen, 2008: p. 144).

Social work intervention needs also to be focused on *preventing* many of the problems faced by migrants. Prevention in social work includes three kinds: preventing problems from occurring in the first place, preventing their escalation, and finally their reoccurrence (Valtonen, 2008). Direct practice and advocacy of the kinds mentioned above would serve to prevent problems faced by migrants in their host societies. Social work also has a role to play in the countries of origin, to address issues of human rights violation, poverty, and underdevelopment, and to ensure an adequate standard of living to prevent persons from leaving the country (Eurodiaconia, n.d.).

Consultations with migrants and service providers have led to the conceptualization of a comprehensive needs-based model for intervention with migrants to meeting both their immediate needs, labor market needs, and ongoing needs that emerge on account of their interactions with the host cultural milieu (George, 2007). The model puts the needs of the migrants at the center of the intervention and proposes that social workers develop expertise at specific levels of intervention. The model suggests three levels of intervention: First, focused on meeting the immediate settlement needs of the migrants; second, focused on helping highly skilled migrants navigate the labor market and its requirements of accreditation and referrals; and third, on providing culturally appropriate intervention to migrants in dealing with issues that arise of the process of settlement such as parent–child conflict, family violence, and mental health (Fong, 2003).

An integrated framework for cross-cultural practice (Tsang and George, 1998) is useful to guide social work intervention with clients from diverse communities. Such a framework avoids essentializing tendencies and emphasizes the need for the appropriate attitudes, knowledge, and skills for cross-cultural practice. Attitudes that are facilitative of good cross-cultural practice include a commitment to justice and equity, the valuing of difference, and openness to cultural difference and learning from the clients and constant critical self-reflection. Effective cross-cultural social work is also characterized by the social worker having knowledge of the systemic context of the host society's culture, of acculturation and internalized culture as well as of the dynamics of cross-cultural communication and understanding. Required skills include the management of one's own emotional response, skills in intervention in institutional contexts, and communication and relationship skills. It is also important for the effective cross-

cultural social worker to utilize research in evaluating the effectiveness of interventions and to identify effective strategies for change (Tsang and George, 1998: p. 7).

Challenges to Social Work Interventions

Interventions with migrants must be informed by an understanding of the manner in which migrant status, in interaction with other markers of identity such as race, gender, ethnicity, and language proficiency, shapes the functioning of migrants. Professional social workers with the knowledge (specialized knowledge in issues related to settlement and an understanding of the intersectional nature of oppressions), skills (in systemic level intervention), and attitudes (an antioppressive framework) could help prevent the problems that migrants face in the settlement and integration process into deteriorating to a point of requiring more intrusive actions.

The dearth of professional social work involvement at the settlement service stage can be attributed to funding limitations; as well as the lack of training for social work with migrants (Yan and Chan, 2010). Few schools of social work offer courses that emphasize skills in working with immigrants and refugees and social workers often lack knowledge of socioeconomic, legal, and advocacy issues surrounding migration (Martinez-Brawley and Zorita, 2010).

Tensions exist between existing dominant discourses targeted at migrants (such as assimilation), and of the principles of social work practice that value self-determination and social justice (Balgopal, 2000). Social workers need to guard against being coerced into surveillance (Humphries, 2004) and policing (Martinez-Brawley and Zorita, 2010: p. 26) of immigrants, and be guided by core values in relation to social justice and integrity in their relationships with migrant clients.

Serving undocumented or 'illegal' migrants presents an ethical dilemma for some social workers (Park and Bhuyan, 2011) as they try to balance the contradictions between serving 'undeserving' populations, and their ethnical obligations to serve all migrants, based on fundamental human rights (Valtonen, 2008; *Official Journal of the European Union*, 2010; United Nations, n.d). Tensions also arise when the policies and laws of the countries stipulate lines of action that are contradictory to client needs or ethical codes of conduct or human rights (Humphries, 2004). The harsh public response to the issue of undocumented workers might lead to a weakened social work response (Valtonen, 2008).

Conclusion

Migration is likely to be an enduring feature of all countries, and especially those that require skilled labor for the advancement of their economy. The problems with settlement especially the labor market integration of migrants are likely to create a class of marginalized individuals in the host societies. Social workers have to address the issues related to the marginalization of this vulnerable group to prevent the loss of human and social capital to the host societies.

Migration: Anthropological Perspectives

Caroline B Brettell, Southern Methodist University, Dallas, TX, USA

© 2015 Elsevier Ltd. All rights reserved.

Abstract

This article traces some of the key developments in the anthropology of migration, focusing particularly on critical trends at the end of the twentieth and the beginning of the twenty-first centuries. Among these are the formulation and analysis of transnationalism; the exploration of processes of inclusion and exclusion, together with new considerations of the meaning of citizenship; the problematization of multiculturalism and hyperdiversity coinciding with a renewed emphasis on the local in relation to the global; and a continued interrogation of the gendered dimensions of migration.

The roots of anthropological research on migrant populations can be found in the early work of urban anthropologists in Africa and Latin America who, in the post-World War II period, began to witness the movement of populations out of rural areas and into the growing cities of the developing world. By the mid-1980s, several key areas of research emerged in a 'new anthropology of migration' that was increasingly focused, although by no means exclusively, on international population flows rather than on internal migration. These areas included the political economy of migration; the social organization of migration, including studies of social networks and immigrant organizations; the relationship between migration and ideology, including gender ideology; and the impact of migration on identity, including ethnic identity.

Although much of the early research on migration that was carried out by anthropologists drew on modernization theory and a bipolar framework of analysis that opposed sending and receiving areas as well as push-and-pull causal factors, these approaches were soon replaced by historical-structural approaches rooted in dependency theory and world systems theory that clearly established the connection between migration and processes of globalization. Additionally, anthropologists began to explore how state policies both shape and are shaped by the international movement of people. The shortcomings of these more macro-level theoretical approaches led, in turn, to the development of theoretical frameworks that could encompass the migrant and/or the migrant household as active agents in the process of migration.

By the early twenty-first century, a large volume of ethnographical work had accumulated from places across the globe, much of it summarized in a host of useful review articles and edited volumes tracing the major contributions of anthropology to the study of migration (see, for example, Brettell, 2008; Fassin, 2011; Foner, 2003; Silverstein, 2005; Vertovec, 2011). The contributions of anthropology to migration studies are many, but since 1990 a number of critical areas have been identifiable. They are the formulation and analysis of transnationalism; an exploration of processes of inclusion and exclusion that has included new considerations of racism and the meanings of citizenship; the problematization of multiculturalism and hyperdiversity coinciding with a renewed emphasis on the local in relation to the global; and a continued interrogation of the gendered dimensions of migration.

The Transnational Dimensions of Migration

At the end of the first decade of the twenty-first century, transnationalism had been identified as "one of the fundamental ways of understanding contemporary migrant practices across the multi-disciplinary field of migration studies" (Vertovec, 2010a, p. 3). Although the transnational framework is central to several disciplines, anthropologists were among the first to recognize its significance. Transnationalism describes a social process, whereby migrants operate in social fields that cross geographic, political, and cultural borders. It therefore offers an alternative to the more linear and one-way theory of assimilation to describe how migrants settle in a host society. From a transnational perspective, migrants are no longer uprooted but are, rather, active participants in both homeland and host societies.

Although certainly a subject of debate (Is it new? Will it last? How widespread is it?), the transnational framework is well suited to the analysis of twenty-first century population movements that are facilitated by improved modes of transportation and impacted by the information and images that can be transmitted rapidly across vast physical distances, thereby reducing the social distance between the homeland and the country of immigration. Anthropologists have conducted research on transnational families and long-distance parenting; transnational political activities and organizations; transnational religious and ritual practices; and the transnational economics associated with remittances and global entrepreneurship. Some anthropologists have addressed the strategic transnational projects of elite migrants (including, by extension, the relationships among migration, transnationalism, and development), but more commonly, the emphasis has been on the everyday transnational actions of working-class migrants as well as on how transnational identities and arrangements may challenge the political and cultural authority of the state as well as state projects concerning immigrant incorporation.

Research on transnational migration has resulted in new multisited methodologies that can encompass the myriad dimensions and spaces that characterize a transnational social field. In an attempt to sort out the complex empirical and methodological reach into transnationalism, Stephen Vertovec (2004, p. 971) has usefully outlined three modes of transformation within three domains: the perceptual, which

involves a migrant's 'orientational bi-focality in the sociocultural domain'; the conceptual, which affects the "meaning of the analytical triad, 'identities-orders-borders' in the political domain"; and the institutional, which affects 'forms of financial transfer, public–private relationships and development in the economic domain.'

Closely associated with work on transnationalism are efforts to re-theorize the concept of diaspora and the diasporic subject. As Pnina Werbner (2004, p. 896) has argued, diasporic communities, as mobilized groups, "are cultural, economic, political and social formations *in process*…. Diasporas are full of division and dissent. At the same time they recognize collective responsibilities, not only to the home country but also to coethnics in far flung places." Anthropologists have explored the process by which diasporas are formed and articulated, whether in real or virtual spaces. Of particular interest is the way in which diasporas nurture collective memory and social solidarity with coethnics dispersed across the globe. Consideration of diaspora has also generated ethnographic work on memory and the meaning of home and/or the idea of return. It has also brought the study of refugees into the arena of the anthropology of migration in order to assess what forcibly displaced populations share with those classified as economic migrants as well as where their experiences differ. In addition, some anthropologists have conducted research into the role of the sending society state in the lives of diasporic populations, promoting the maintenance of cultural practices and religious observances, facilitating remittances that are fundamental to sending society economies, or even establishing, as in the case of Haiti, an official political status for their nationals living abroad.

In summary, the anthropological work on transnationalism and diasporic communities emphasizes the way in which identities are negotiated and constructed simultaneously in local, national and global spaces. Transnationalism encompasses displacement and emplacement, deterritorialization and reterritorialization, the transgression and redefinition of borders, and the construction and deconstruction of boundaries. The transnational and diasporic practices of migrants are both influenced by and in turn influence broader processes of global change. Both are likely to continue and continue to be the object of anthropological inquiry.

Claiming Inclusion: The Politics of Citizenship and Belonging

The transnational framework has resulted in a host of new and innovative approaches to the concept of citizenship, a topic with which anthropologists have only recently become engaged. As Michel Laguerre (1998, p. 177) has observed, "given the fact that these transnational practices occur on an everyday basis, it seems that our concept of citizenship is no longer consistent with the domain of practice." Laguerre formulates the concept of diasporic citizenship to capture the "situation of the individual who lives outside the boundaries of the nation state to which he or she had formerly held primary allegiance and who experiences through transnational migration….the subjective reality of belonging to two or more nation-states" (pp. 12–13). Other anthropologists working on migrant populations write of transborder citizenship, flexible citizenship, racialized citizenship, or polycultural citizenship, all with the goal of emphasizing that citizenship is more than simply a political status or a set of rights and obligations between individuals and the state. Rather it is "a total relationship, inflected by identity, social positioning, cultural assumptions, institutional practices and a sense of belonging" (Werbner and Yuval-Davis, 1999, p. 4). Thus, a critical question for anthropologists is how citizenship is claimed or negotiated by migrants who are often confronted with acts of exclusion whether more formally by nation states or more informally in the context of everyday interactions (Reed-Danahay and Brettell, 2008).

To capture this sense of belonging, and of citizenship as practice, several anthropologists have operationalized a concept of cultural citizenship that has been defined on the one hand as a process of subjectification and citizen-making and, on the other hand, as a process whereby immigrants can claim space and inclusion. As an example of the first approach, Aihwa Ong (2003, p. 15) shows how Cambodian Americans experience American citizenship by illustrating the "social policies and practices beyond the state that in myriad mundane ways suggest, define, and direct adherence to democratic, racial and market norms of belonging." She suggests that it is in the spaces of encounter, "in the practices directed at newcomers, and the mutual daily interactions that ensue, that the meaning and exercise of citizenship happens" (p. 16). By contrast, the second approach to cultural citizenship highlights the more agentic dimensions of belonging – that is, claiming "the right to be different (in terms of race, ethnicity, or native language) with respect to the norms of the dominant national community, without compromising one's right to belong, in the sense of participating in the nation-state's democratic processes" (Rosaldo and Flores, 1997, p. 57). Anthropologists have drawn on this formulation of cultural citizenship to explore various forms of political activism and immigrant civic engagement as well as dimensions of immigrant youth culture. Much of this work emphasizes that the expression of citizenship among immigrants and their offspring is fluid and changing, multidimensional, subjective, and often contentious.

Confronting Exclusion: Racism, National Identity, and Constructions of the Immigrant 'Other'

Anthropologists have recognized, documented, and theorized the various ways in which migrants are made into citizens or make claims to citizenship and hence inclusion, but at the same time, they have also explored concomitant processes of exclusion. Here they have focused attention on the reception of immigrants, particularly how immigrants are constructed as being 'foreign' and 'other' in public discourse. Beginning in the 1990s, particularly in the new host societies of southern Europe, foreigners were often represented as morally degenerate criminals and were frequently associated with drug smuggling and sexual trafficking. But such processes of negative stereotyping and othering have been identified as equally characteristic of the United States, a country with a deep history of immigration. Thus, the Cuban refugees who arrived as part of the Mariel boatlift were stigmatized as criminals, homosexuals, and communists, while Haitians were stigmatized as

carriers of HIV/AIDS. Needless to say, racism was also in play in relation to both these populations, the Marielito Cubans being decidedly darker than the first wave of Cuban refugees who fled to the United States in the early 1960s.

In the European context, anthropologists have drawn attention to a 'new racism' based on cultural difference (Silverstein, 2005; Vertovec, 2011), particularly in relation to migrants of Islamic background (Mandel, 2008), but also in relation to those seeking political asylum (Fassin, 2005). In his analysis of the 2004 law in France that banned the wearing of head scarves in public schools, John Bowen (2007) argues not only that critical dimensions of French identity (secularism and communalism) were and continue to be at the center of this debate but also that the law itself illustrates the "particularly French passion for seeking statutory solutions to social ills" (p. 243). Bowen, as well as several other anthropologists working on the subject of immigrants in Europe, pay particular attention to the role of the media in constructing particular representations of foreigners, especially Muslims. This role includes, in Bowen's view, one in which Muslims are accorded the right to speak (p. 246) and hence what kind of Muslim is found to be acceptable in a country (in this case, France) that emphasizes assimilation rather than multiculturalism.

In the United States, it is not the so-called Islamic threat but the Latino threat (Chavez, 2008) that anthropologists have identified as a primary motivation for anti-immigrant discourse and processes of exclusion. Equally important are the debates over illegality, which some anthropologists have formulated as a state of abjectivity – being cast away as low, contemptible, and undeserving beings (Gonzales and Chavez, 2012). In her ethnographic study of undocumented Salvadorans in the United States, Susan Bibler Coutin (2003, p. 29 ff) captures this abject status in her reference to the spaces of nonexistence that this population occupies. 'The undocumented therefore exist in a non-domain, a space of illegality. Often conflated with criminals, unauthorized immigrants are officially outside both the law and the social body.' Based on his research on immigration to Bahrain, Gardner (2010, p. 52) has observed that "attention to illegality, deportation, and removal focuses the anthropological lens on the processes by which states seek to control the movement of people in particular… Illegality, deportation and other forms of removal are tools the state uses to control and govern the transnational movement of people." All of this work (see also Ticktin's (2011) discussion of the *sans-papiers* in France), ultimately rooted in the theoretical frameworks of governmentality formulated by Michel Foucault, reflects the ways in which the anthropology of the state intersects with the anthropology of migration. Further, it allows anthropologists to investigate the relationship between migration and constructions of national identity. What makes people American, or French, or Italian, or Australian, or Canadian is often given salience in debates that circulate around the immigrant other.

Cities, Hyperdiversity, and the Multicultural Project

The individual, the household, and the state are all important units of analysis in the anthropology of migration. But recently, anthropologists have refocused their attention on the urban context where the majority of migrants settle, thereby returning in some sense to the roots of the anthropology of migration in the development of urban anthropology. Anthropologists have emphasized a 'city as context' perspective not only as a way of framing a more comparative approach to the study of processes of migrant settlement but also as a way of linking macro and micro processes. By focusing on the city as a unit of analysis, anthropologists can explore the nuances and dynamics of intergroup relations as well as how race and ethnicity are constructed and negotiated in everyday life and everyday practice. Cities differ, for example, in the historical depth of their experience with immigrants, in the diversity of the immigrant populations that settle there, in their geographical characteristics, in their local economies, and in their political structures.

Emerging from this renewed interest in studying the city as one studies migration is a focus on how the scale of a city impacts processes of migrant incorporation and transnational connection. This approach is offered as an alternative to the methodological nationalism reflected in studies that emphasize ethnic groups, ethnic institutions, and nation-states. Rather than to view cities simply as 'containers, providing spaces in which migrants settle and make a living,' the city-scale approach highlights how migrants 'actively contribute to the restructuring and repositioning of either their cities of settlement or those to which they are transnationally connected' (Glick Schiller and Caglar, 2011, p. 2, 3). Migrants, from this perspective, are both subjects and agents of the global processes, including neoliberal restructuring, that reposition cities and other local places. Those who have adopted this scalar approach are calling for "a theory-inspired comparative agenda that will advance conceptual and empirical knowledge on urban and migrant dynamics" (Glick Schiller and Caglar, 2011, p. 19).

Another area of interest that has emerged from the renewed interest in cities as units of analysis in the anthropological study of migration is that of super- or hyperdiversity within national and particularly urban environments. Vertovec (2010b, p. 66–67) describes this approach as drawing on previous work concerning multiethnic arenas of interaction, residential segregation, notions of pluralism, and the complex and multilayered experience of migrants with unequal power structures and social locations. It is an approach that looks at diversity from a variety of perspectives by considering its multiple dimensions and the range of factors that influence people's lives in local places. Of particular note is that multiculturalism from this perspective can be viewed as a "kind of diversity management strategy" (p. 68).

A recent example of ethnographical work that examines how people come together in a multi-ethnic city to construct a collective life is Beth Epstein's (2011) study of the state-planned new town of Cergy in the suburbs of Paris. Multiculturalism is at the center of her analysis. "In Cergy, as in other cities in France, the question of how best to integrate people of foreign origin into the local design is being posed in relation to larger anxieties about how best to build and sustain a cohesive social fabric in a period marked by a preeminent concern for the problems of insecurity and social dissolution…. The discursive shift, led by members of self-styled minority groups….[draws] attention to the way integration can act as

a discriminating force that selects and chooses, even as it strives to create an ostensibly universal, cohesive whole" (Epstein, 2011, p. 162–163). Epstein offers us what she labels a "cultural analysis of the politics of integration" (p. 19).

Some anthropologists have framed multiculturalism positively as a policy that respects diversity and difference, whereas others have emphasized the negative dimensions in relation to a 'moral panic' about an 'excess of alterity' (Grillo, 2010). The work of Norwegian anthropologist Unni Wikan (2002) is notable here. She argues that the multicultural model and its 'excessive tolerance' for difference has resulted in a 'generous betrayal' of immigrant newcomers. Culture, in her view, has become a bit like race, a concept that subverts human rights, particularly those of women and children, because it supports ethnic differences and identity politics. Writing about Norwegians, but one could extend this category, Wikan suggests that they regard one another "as individuals with a different character and the ability and will to think for themselves." By contrast, she argues, "immigrants are largely perceived as products of culture. They are perceived as caught in the grips of culture and therefore unable to exercise independent judgment… It is disrespectful and really quite degrading. Unfortunately, immigrants themselves often contribute to such degradation. By constantly invoking 'culture' as explanation (and excuse) for their behavior, they belittle themselves as acting, thinking, willful human beings, and they run down the very qualities that have brought them here: initiative, courage, perseverance" (Wikan, 2002, p. 81). Wikan offers a powerful critique of the concept of culture and of a multicultural model of integration that ignores intracultural variability. Several other European ethnographers have followed Wikan's lead by noting and critically analyzing the expanded use of the concept of culture in public discourse in relation to debates about immigrants and ethnic minorities (see Vertovec, 2011).

In a more recent book, *In Honor of Fadime*, Wikan (2008) pursues this interest by offering a nuanced analysis of the so-called honor killing, in 2002, of a young Kurdish woman born and raised in Sweden. She juxtaposes the argument that many immigrants have not left their respective countries voluntarily and hence have not made a conscious choice to abandon their cultural traditions, with the rights of children who are born abroad and whose identities and cultural choices may be more in line with those of liberal western democracies. Governments of host countries must, in her view, be sensitive to the conflicts and human tragedies that can emerge from this situation and to the fact that culture is neither static nor inherited but, rather, is composed of a multiplicity of views (including those of parents and children) and is always changing. Her conclusion, applied to Norway but with broader implications, is that "the critique of the culture concept that is engaging anthropology must be applied with equal force to the situation of immigrants…. Otherwise the result will be racism – wielded in the name of charity" (2002, p. 83).

Gender and Migration

The attention that Wikan's work draws to honor killing and, for that matter, the larger debates about cultural practices (veiling, female circumcision, polygyny) that are out of place in European host societies, underscore the importance of the gendered dimensions of migration. Interest in the relationship between migration and gender emerged in the 1970s with the development of feminist anthropology and coincided with the growing feminization of migration that has been noted by demographers. Anthropological studies of gender and migration emphasize how men and women are both gendered actors in the migration process, equally affected by global gendered processes and gendered institutional structures. This corpus of research pays particular attention to how patriarchal structures can affect work, family life, associational life, welfare state policies, and labor recruitment policies in both the sending and the receiving societies. Gender ideologies can impact the possibility of migration, the processes of incorporation, and how individuals (men and women) engage in transnational space.

Two ethnographic examples illustrate the significant variation in gendered dimensions of migration. Mexico is characterized by a gendered culture of migration. Despite the increasing number of female migrants to the United States, Mexican men and women continue to define migration flows as primarily male because that is what is compatible with local understandings of gender and masculinity (Malkin, 2004). Further, while el Norte is defined as the place of work, Mexico is defined as the place of family and of life. By contrast, in Sri Lanka it is primarily women who depart to work as housemaids in the Middle East and men who remain behind and take over child care and other kinship tasks (Gamburd, 2008). Approximately 10% of Sri Lankan households have an adult female who is working overseas. "Labor flows from sending countries that depend on family structures that facilitate migration, and demands for labor in host countries rely on cultural assumptions about the gender, race, religion, and other characteristics of the ideal worker" (Gamburd, 2008, p. 7). In Sri Lanka, family structure (and we might argue, by extension, gender relations) is less the result of traditional forms of organization than of constant adjustments to changing circumstances, locally, nationally, and globally. When these Sri Lankan women breadwinners return from abroad with their experiences of cosmopolitanism, they often face backlash and are subjected to accusations of prostitution and marital infidelity while abroad. As a result they resist trying to change local hierarchies once they return in order to subvert these accusations and the sometimes violent behavior that accompanies them.

The literature concerning gender, migration, and the family also documents how gender roles and relationships that have been constructed in particular and differing cultural contexts are either reproduced or transformed in the immigrant context. A number of scholars, for example, have explored how the increasing economic responsibilities of immigrant women have impacted gender hierarchies within the family. Commonly, marital conflicts and tensions result from the discrepancy between the traditional patriarchal ideology that may be held by husbands and the important economic contributions of their wives to the maintenance of the immigrant household. In many cases, however, women's challenges to male authority within the family are subtle, and generally economic resources are pooled. In other cases, a more

companionate form of marriage emerges as a result of migration (Hirsch, 2003).

Finally, it is important to emphasize the new work on gender and migration that intersects with medical anthropology and with humanitarian concerns. A number of anthropologists have focused on women's health issues; on the exclusionary policies related to the reproduction, including the move away from birthright citizenship in Ireland or the controversies over 'anchor babies' in the United States; on the relationship between migration and the spread of HIV/AIDS in various parts of the world; and on violence against women. In a particularly intriguing approach to these issues, Ticktin (2011, p. 129) demonstrates how "sexual violence renders legitimate the claim for papers and basic rights" in a broader context that is blatantly anti-immigrant. Ticktin's larger argument is that a regime of care plays an important role in the politics of immigration such that battered women or immigrants who are sick can make legitimate claims for crossing borders while those who are simply fleeing poverty cannot.

Conclusion

Anthropological research on population flows, whether internal or international, is diverse in the questions that are pursued and the methodologies that are deployed. What is common to all this work is a sensitivity to place and context as well as an awareness of the importance of documenting and analyzing the multifaceted ways in which people in local places respond to global processes. Anthropologists remain attentive to the importance of culture, which means that they highlight the relationships between beliefs and behaviors; the interactions among the multiple dimensions (economic, religious, political, and social) of the human experience; and the importance of issues of identity that are fluid and constantly negotiated. Anthropologists of migration also remain attentive to the comparative approach that has been central to their discipline and thus pursue questions not only of what is common to the migrant experience, no matter where migrants originate from and what their destination might be, but also of what is unique and why. Finally, it is important to emphasize that the anthropology of migration intersects with other anthropologies, for example, with feminist anthropology, the anthropology of the state, the anthropology of globalization, and medical anthropology. These intersections enrich the theoretical frameworks and empirical dimensions of the anthropological study of migrant populations.

Migration: Cultural Aspects

Marcelo M Suárez-Orozco, Graduate School of Education and Information Studies, University of California, Los Angeles, CA, USA

Abstract

In the twenty-first century migration is the human face of globalization. All continents are experiencing mass migration – as sending, transit, or destination areas, and often, all three at once. This article reviews the basic scholarship on cultural concerns in mass migration with a focus on families, language, and inequality, as they structure the pathways of immigrants in a variety of destinations.

Introduction

As we enter the second decade of the twenty-first century, the lives over a billion people are shaped by the experience of migration. All continents are involved in the massive movement of people, as areas of immigration, emigration, or transit – and often as all three at once. In the twenty-first century, immigration is the human face of globalization – the sounds, colors, and smells of a miniaturized, interconnected, and fragile world. But viewed anthropologically, immigration is constitutive of the human experience. Migration is written in our genetic code and is encoded in our bodies: in our bipedalism, in our stereoscopic vision, in our neocortex. Modern humans are the children of immigration, and migrations today are transforming humanity. During second decade of the twenty-first century, 232 million are international migrants (see http://data.worldbank.org/indicator/SM.POP.TOTL), approximately 740 million as internal migrants (UNDP 2013 http://www.un.org/en/development/desa/population/publications/pdf/technical/TP2013-1.pdf) and millions more as immediate relatives left behind (UNDP, 2010). Only China (1.36 billion) and India (1.4 billion) have larger populations than this immigration nation.

Mass migrations have ushered in the era of hyperdiversity. The global cities of the twenty-first century now resemble the breathtaking cultural and linguistic diversity once associated with the highlands of New Guinea or the Amazonian Mato Grosso. There are now over a dozen global cities with more than 1 million immigrants – from Hong Kong to Melbourne, from Moscow to Singapore, and in more than two dozen global cities, immigrants now account for more than one-quarter of the population, inter alia, in Amsterdam, Auckland, Muscat, and Perth (see http://www.migrationinformation.org/datahub/gcmm.cfm#map1list).

Globalization increases inequality (Picketty, 2014) and structures migratory flows by coordinating markets, economies, social practices, and cultural models. Demographic and ecological factors also structure mass migration. The number of international migrants continues to grow at a steady rate, and shall likely pass the 400 million mark by 2050, "as a result of growing demographic disparities, the effects of environmental changes, new global political and economic dynamics, technological revolutions and social networks" (International Organization for Migration 2010: p. xix). Lastly, catastrophic migrations related to war and environmental collapses are at an all time high since the second war world. According to the UN refugee agency "the number of refugees, asylum-seekers and internally displaced people worldwide has, for the first time in the post-World War II era, exceeded 50 million people. http://www.unhcr.org/53a155bc6.html"

Viewed anthropologically, immigration involves change in residency and change in community. Scholarly research has specialized in two broad types of large-scale migration: internal migration (within the confines of a nation-state or territory) and international migration (across international borders). Although the large-scale movement of people within a nation-state is a phenomenon of a separate order from mass migrations across international borders, internal migrants share many characteristics with international migrants: most move from rural villages to urban centers, many experience linguistic and cultural dislocations, racialization, and face isomorphic bureaucratic and legal restrictions. Much scholarly and policy attention has been focused on international migration. Yet most migrants are internal migrants staying within the confines of their nation-states. India and China, following their insertion into global capitalism, have experienced unprecedented levels of internal migration. With more than 320 million migrants in India and over 200 million in China, the two countries combined now have more than double the number of international migrants the world over. Some of the most important anthropological contributions to the study of immigration have focused on internal migration (for example, Colson, 1971; Brandes, 1975; Scudder and Colson, 1982; Morgan and Colson, 1987).

Mass migration is reshaping economies and societies the world over, yet many facets of immigration remain overlooked, misunderstood, or neglected. The dominant approaches to the study of mass migration privilege labor factors (Piore, 1980); economic variables (Borjas, 1999); demographic forces (Passel and Cohn, 2009); and, in recent years, border controls, security (Andreas, 2009), and undocumented immigration (Massey et al., 2002; Chavez, 1997). Though these approaches have generated some scholarly consensus, important aspects of mass migration remain unexplored. In this article, I first examine cultural concerns in immigration *qua* the family, and then I turn to concerns over immigration and language. This by necessity will lead us to examine current debates in the educational literature on the nexus between immigration, language acquisition, and education. Lastly, I will briefly examine concerns over immigration and inequality through the lenses of poverty, segregation, unauthorized status, and racialization.

Immigration and the Family

The unit of migration is the family – variously defined in different parts of the world and structured by distinct culturally coded legislative, economic, reproductive, and symbolic forms. Immigration is an ethical act of and for the family. Distinct patterns of kinship, household, family, and social organization are of paramount importance in structuring worldwide migratory waves (Massey, 1990). Immigration typically starts with the family and family bonds sustain it. Immigration profoundly challenges and changes families as well as the societies in which immigrants settle (Foner, 2009).

Historically, the pattern in stepwise migration was of the male going ahead, establishing a beachhead while sending remittances home. Over time, when financially possible the process of bringing relatives – wife, children, and others – begins. But in recent decades, immigration has achieved a nearly perfect gender balance with approximately half of all global migrants being women. In the high- and middle-income countries, demand for service workers draw women – many of them mothers – to care for children. In rapidly aging countries it is equally true that these immigrant workers are summoned to care for aging folks. Immigrant care labor is thus present at the start and the end of the life cycle.

With large-scale migration, transnational families have entered the global cities of the twenty-first century. For millions 'home' – as a cultural ideal and *qua* the practices of the household may be in two countries. Anthropologists have pioneered the scholarly study of migrants shuttling back and forth in transnational labor and living arrangements the world over (Basch et al., 1994). Transnational migrants remain substantially engaged (economically, politically, and culturally) in their newly adopted lands and in their communities of origin, moving back and forth in ways not always seen in previous eras of large-scale immigration (Suárez-Orozco and Suárez-Orozco, 2001). Millions of children throughout the world are being raised transnationally.

The transnational lives of immigrant families have only recently come into scholarly focus. On the basis of a study of schools in the states of Nuevo Leon and Zacatecas, Hamann and Zuñiga (2008) estimated that as much as 2% of students enrolled in Mexico's *primarias* (primary schools) and *secundarias* (high schools) had transnational experiences, including considerable schooling in the United States. Approximately half of the transnational youth in this study were born in the United States or had a US-born mother. The authors suggest that perhaps 1%, or as many as 220 000, youth being educated in Mexico, are in fact US citizens living transnational lives.

Millions of other children are educated in culturally patterned long-distance family arrangements where separations and reunifications across national boundaries are normative. In a recent study conducted in Montreal, among 254 first- and second-generation immigrant-origin youth from the Philippines and the Caribbean, approximately 62% of the Filipino-origin participants and 38% of the Caribbean-origin participants had experienced separations during their migration (Rousseau et al., 2009). In a nationally representative survey of 1772 youth that restricted its sample to documented immigrants, nearly one-third of the participants between ages 6 and 18 years had been transnationally separated from at least one parent for two or more years (Gindling and Poggio, 2009). Notably, the rates of separation were highest for children of Latin American origin, which happen to be more than half of all migrants to the United States. This is a low estimate since separation rates are higher among the unauthorized or those who are in the process of regulating their documentation status.

The Longitudinal Immigrant Adaptation Study (LISA) found high rates of transnational family separations among new immigrant students. This US bicoastal interdisciplinary study was conducted with 400 recently arrived immigrant youth from China, the Dominican Republic, various countries in Central America, Haiti, and Mexico recruited from public schools; Suárez-Orozco et al. (2008) found that nearly three-quarters of the youth were separated from one or both of their parents during the migration process. There were significant differences between immigrant groups in regards to family separation: Chinese families were least likely to be separated over the course of migration (52%), whereas the vast majority of Central American (88%) and Haitian children (85%) were separated from either one or both of their parents during the course of migration. Approximately 26% of children in the study were separated from both parents, a pattern most often occurring in Central American families (54%). The length of separation from parents was unexpectedly long: some individuals in the study reported being separated from one or both parents for nearly their entire childhood, though the length of separation varied widely across regions of origin. Of the youth who were separated only from their mothers, 54% of Central American children endured separations lasting 4 years or more, as did approximately one-third of both the Dominican and Haitian families. Chinese and Mexican children underwent fewer and shorter separations from their mothers. When separations from the fathers occurred during migration, they were often very lengthy or permanent ones. For those families who were separated, 28% had separations from fathers that lasted more than 4 years. Notably, the LISA study found that immigrant youth who underwent protracted family separations and complicated reunifications were at higher risk to show a pattern of declining academic achievement over time once they resettled in the new country (Suárez-Orozco et al., 2010a).

Recent scholarly work has identified a related pattern of 'satellite children' born in the Untied States to immigrant parents but raised by grandparents in China. A study of immigrants in New York City estimated that more than 50% of the mothers had sent their youngsters to Fujian Province to be raised by grandparents. The mothers reported undocumented status, substantial immigration-related debt burdens, and exhausting 6-day work weeks as the main reasons for raising their children transnationally (Kwong et al., 2010, Yoshikawa, 2011). Many of these transnationally raised children, the mothers expected, would return to the United States to complete their formal education.

New research suggests that migrations resulting in protracted separations threaten the identity and cohesion of the family, transforming well-established roles, creating new loyalties and bonds, and destabilizing cultural scripts of authority, reciprocity, and responsibility (Suárez-Orozco and Suárez-Orozco, 2011). Even under the best of circumstances, the family is never the same after migration. One family

commences the migratory journey and 'another,' now reconstituted family, completes it.

Immigration, Language, and Schooling

The children of immigrants are the fruit borne of immigration (Suárez-Orozco and Suárez-Orozco, 2001). Immigrant-origin children are a fast-growing sector of the youth population in diverse countries the world over, including Australia, Canada, Germany, Italy, New Zealand, the Netherlands, Spain, and Sweden (Meir and Morehouse, 2008). In the United States, the country with the largest number of immigrants in the world (at more than 42 million in 2014), approximately one-quarter of all youth are of immigrant origin (more than 16.6 million in 2010), and it is projected that by 2020 one in three of all children will be growing up in immigrant households (Frey, 2011). The transition of immigrant-origin children to an ever-larger list of immigrant-dependent countries is a topic of scholarly interest, policy relevance, and practical urgency.

As families migrate, their languages move with them, leading to greater linguistic and cultural diversity. The new hyperdiversity challenges modernist ideologies linking identity and belonging to a single national language and cultural tradition. In the United States, immigrants speak a combined total of more than 460 different languages (Kindler, 2002). In New York City, approximately half of all children and youth originate in immigrant-headed households speaking an estimated combined 176 different languages (see http://www.nytimes.com/2010/04/29/nyregion/29lost.html?_r1). In Los Angeles Unified School District, the nation's second largest, over 62% of the children and youth are English Language learners (see http://dq.cde.ca.gov/dataquest/lc/DistrictLC.aspx?cYear=2013-14&cSelect=1964733–LOS+ANGELES+UNIFIED).

How to best develop the means to communicate in the dominant language, thereby developing advanced academic language skills required for higher-order cognitive work and the matter of maintaining immigrant languages are fiercely debated the world over (McAndrew, 2007). Language acquisition and academic trajectories are bound together with processes of identity formation, acculturation, assimilation, and economic integration (Suárez-Orozco, 1989, 1991; Portes and Zhou, 1993; Portes and Fernández-Kelly, 2008; Portes and Hao, 1998, 2002; Suárez-Orozco et al., 2008).

Two constants have defined the relationship between immigration and language. First, every wave of large-scale immigration in multiple destinations generates a fear that new immigrants will not learn the dominant language. Second, the children of immigrants from widely divergent origins inevitably gravitate toward the new language (Tse, 2001; Portes and Hao, 2002) and, over time and across generations, lose their native language skills (Fillmore, 1991). Yet these mutually canceling concerns miss the defining element of mass migration in the era of globalization: Academic language learning as a cultural construct is changing what is required in terms of language acquisition for this generation of immigrants. Most large-scale studies of immigrants depend on self-reported data of oral proficiency, which differs from the decontextualized, written language necessary for higher-order cognitive engagement and academic success (Cummins, 2000).

Academic language proficiency is central to any understanding of educational trajectories of immigrant youth in high-income countries with strict accountability regimes of the high-stakes-testing variety. Scholarly research has shown a high correlation between proficiency in academic language skill and academic achievement as measured by standardized tests (Valdes, 2004; Suárez-Orozco et al., 2008). First- and second-generation immigrant youth are often found to score lower than their native-born peers on standardized tests in the United States as well as in European contexts (Barth et al., 2008). The science results of PISA's 2006 study by the Organization for Economic Development and Cooperation (OECD) of 57 countries revealed that, "[i]n fact, first-generation immigrant students in OECD countries lag on average more than 50 lconsidering the OECD average difference in performance between school years" (Christensen and Segeritz, 2008: pp. 13–14). Likewise, the 2006 math and reading results show that "the achievement gaps for immigrant and nonimmigrant students in reading and mathematics in 2006 are similar to those found in science in 2006" (Christensen and Segeritz, 2008: p. 15). Although there are cross-country differences in the academic trajectories of immigrant-origin youth (Christensen and Segeritz, 2008) and although, over time, some immigrant-origin youth do remarkably well (Kasinitz et al., 2008), the general trend is worrisome, especially as the share of immigrant-origin students continues to grow in a number of countries.

Research on second-language acquisition and bilingualism informs debates on educational models that promote success for immigrant youth, especially which language should be used for instruction, under what circumstances, and for how long. One recurring finding (Cummins, 2000; Collier, 1995; August and Hakuta, 1997; Hakuta et al., 2000) is that it takes approximately five to seven years for immigrant language learners to develop the academic language proficiency required to compete fairly with native speakers in standardized-assessment regimes at the center of education reforms the world over. Another consistent finding suggests that 'balanced biliguals' that is, youth who maintain their home language as they acquire a second academic language, tend to have better educational trajectories over time (Portes and Rumbaut, 2001).

Immigration and Inequality

In the age of linguistic and cultural hyperdiversity, there is considerable heterogeneity in socioeconomic status between and within immigrant groups. Immigrants today, unlike in previous eras of mass migration, are among the most highly educated and skilled workers in their new countries. Never before in world history have so many highly educated and skilled people joined the migration flow in such high numbers. This is true in the United States, as well as in Canada, Australia, New Zealand, and other destinations, where immigrant-origin scientists, engineers, and medical doctors are overrepresented as a total share of the population (see Migration Information Source 2010; http://www.migrationinformation.org/Feature/display.cfm?ID 779).

Immigrants seldom originate in the poorest regions of the world, yet research suggests that they are more likely than their

native counterparts to encounter poverty in their new societies (Kazemipur and Halli, 2001). Poverty, defined as a 'condition of relative deprivation within society' (Kurtz 1973: p. 53), is created in part by unique disadvantages that are often associated with immigrant status, such as "language barriers, incompatibility of educational credentials, limited transferability of job skills, unfamiliarity with the market demands, and lack of access to job and educational networks" (Kazemipur and Halli, 2001: p. 1132; de Haan and Yaqub, 2009).

Concerns over the transgenerational transfer of poverty among immigrants have lead to research examining poverty in immigrant families and children. The children of immigrants have "greater market-income poverty rates than children in native-born families" (Hernandez et al., 2010: p. 425). In affluent countries worldwide, poverty among children of immigrants has increased steadily in recent years with gaps between native-born and immigrants ranging from 7% in Australia and Germany to 12% in the United States and to 26–28% in England and France (Hernandez et al., 2010). Differences among ethnic groups are also prevalent. US data on Latino children show that, in 1999, 22.8% were living in poverty, compared with 7.7% of whites (Therrien and Ramirez, 2000). In 2006, however, the poverty rate for Latino children had nearly doubled that of white native-born children (28% and 16%, respectively) (Fry and Gonzales, 2008). For immigrant Latino families, poverty rates reach higher percentages, with 35% of foreign-born Latino immigrants living in poverty compared with 27% of their second- or third-generation counterparts (Fry and Gonzales, 2008).

In the United States, children of immigrants are four times as likely as native-born children to live in crowded housing conditions and three times as likely to be uninsured, and 37% of Latino immigrant families report difficulties affording food (Capps, 2001). Children raised in poverty are vulnerable to an array of distresses including difficulties concentrating and sleeping, anxiety and depression, as well as a heightened exposure to delinquency and violence. Poverty has long been recognized as a significant risk factor for poor educational outcomes (Weissbourd, 1996; Luthar, 1999).

Poverty coexists with a variety of other factors that augment risks, such as single parenthood; residence in violence-ridden neighborhoods, gang activity, and drug trade; as well as school environments that are segregated, overcrowded, understaffed, and poorly funded. Poverty, however, is not solely an inner-city phenomenon. In the United States since the 1990s, poverty grew in the suburbs for the first time and at a greater rate than in cities (Murphy, 2010). Poverty is also associated with high rates of housing mobility and concurrent school transitions that can be highly disruptive to educational performance (Gándara and Contreras, 2009).

Immigrant origin Latino children are the most segregated students in US schools (Orfield and Lee, 2005). Immigrants who settle in predominantly minority neighborhoods may have little, if any, direct, continous, and intimate contact with peers from the nonimmigrant mainstream population. A pattern of triple segregation – by race, language, and poverty – shapes the lives of many new immigrants in varied countries.

In Germany, immigration accounts for a significant share of the population. In 2005, approximately 15.3 million people were immigrants or of migrant background. Immigrants are largely segregated, with most immigrant-origin people concentrating in the western part of the country and only a small share living in the eastern states (Clauss and Nauck, 2010).

Povery and segration are often compounded by unautorized status. The United Nations estimates that there are between 40 and 50 million unauthorized migrants worldwide (UNDP, 2010). The United States has the largest concentration of undocumented immigrants in the world – approximately 11 million people are unauthorized. There are approximately 1.1 million youth living in the United States without proper documentation, and millions more are living in households headed by at least one undocumented immigrant (see http://pewhispanic.org/reports/report.php?ReportID61). Research suggests that undocumented youth often arrive after multiple family separations and traumatic border crossings (Suarez-Orozco, 2014 – http://www.pass.va/content/dam/scienzesociali/pdf/ninosmigrantes.pdf); they may continue to experience fear and anxiety about being apprehended, separated again from their parents, and deported (Suárez-Orozco et al., 2008; Chaudry et al., 2010).

A large proportion of undocumented workers are employed in low-paying professions with erratic working conditions (Capps, 2001; Gándara and Contreras, 2009; Yoshikawa, 2011). Unauthorized migrants do not access social services that could serve to mitigate the harshest conditions of their poverty (Yoshikawa, 2011). Psychological and emotional duress takes a toll on the experiences of youth raised in the shadow of the law (Cervantes et al., 2010), which has also been documented through narrative and qualitative research (Bagley and Castro-Salazar, 2010; Suarez-Orozco, 1989; Gonzalez, 2009).

Protracted poverty, deep segregation, and unauthorized status are the ingredients for immigration distopia in many immigrant-affected societies. At the very least, structural factors accelerate the processes of racialization via cultural disparagement (De Vos and Suárez-Orozco, 2000) and negative 'social mirroring' (Suárez-Orozco, 2004) of new immigrants of color.

The arrival of large numbers of immigrants into the high-income countries of the world has resulted in isomorphic patterns of residential segregation and can be related to broader dynamics of racialization of 'marked' native minorities. The idea of 'race,' the stepchild of nineteenth-century pseudoscience, included in these earlier iterations craniometrics (measuring of skulls) as a means of classifying groups of people (Mosse 1964: p. 89) into fixed hierarchical relationships of superiority and inferiority (Gould, 1996; De Vos and Wagatsuma, 1972). As Boas (1940) observed, "a stratification of society in social groups that are racial in character will always lead to racial discrimination. As in all other sharp social groupings the individual is not judged as an individual but as a member of his class" (pp. 16–17).

Racialized hierarchies lent the aura of science to atavistic superstitions that clustered people of 'purer' origin to avoid the danger of contamination by outsiders (Zollschan cited in Mosse, 2000: pp. 201–202). As applied to immigrants, 'racialization' (Bashi, 1998; Omi and Winant, 1994; Shih, 2008) is an appropriate construct foregrounding the sociohistorical processes of segregation, marginalization, micro- and macro-aggressions, and collective disenfranchisement.

In countries such as the United States, large and growing numbers of poor immigrants of color and the undocumented are *de facto* relegated to spaces where socially constructed phenotype (Gilman, 2000; Bonilla-Silva, 2004) aligns with entrenched patterns of segregation and marginalization of native minorities (Corni, 2002; Ogbu and Simmons, 1998; Vigil, 2002). Portes and Zhou (1993; Portes, 1996) have appropriately termed this dynamic as 'segmented assimilation' wherein certain immigrants join the marginalized space of native minorities creating what they term a new 'rainbow underclass.' Meanwhile, other countries have witnessed the emergence of a complex interweaving of factors racializing immigrants and other minorities. These can include religion (France and its North African minorities), country of origin (Japan and its Brazilian, Korean, and other minorities), and social class (Spain and its Roma minority).

In the currency of racialization, dark-skinned immigrants appear to pay a hefty penalty in the US education system. Murguia and Telles (1996) working with the National Chicano Survey report that 10.2% of light-skinned Mexican Americans completed college as opposed to 5.3% among dark-skinned Mexican Americans. Massey and Denton (1989) analyzing US census data report that it will be more difficult for darker-skinned Hispanics than for their lighter-skinned counterparts to integrate into white communities. Color and poverty are correlated with a host of other factors shaping educational trajectories.

Restricted mobility (Massey and Denton, 1989), negative social mirroring (Suárez-Orozco, 2004), and inequitable access to quality education (Orfield and Lee, 2005) among immigrants are not isolated US phenomenona, as the cases of Koreans and other minorities in Japan (Lee and DeVos, 1981; Castro-Vazquez, 2009) and of Europe and its Muslim minorities attest.

To paraphrase Lévi-Strauss, immigration is 'good to think' and interrogate schemas and practices of the modernist nation-state. Transnational displacements bring race, language, and identity to the forefront, interrupting the taken-for-granted cultural schemas and social practices that structure belonging to and membership in the nation. Indeed, the institutions of state-making in the modernist era are geared toward producing citizens, workers, and consumers of a nation-state rather than dual citizens with global sensibilities. Reimagining the narrative of beloging and recalibering the instutitions of the nation state are a *sine-qua-non* to move beyond the current global immigration distopia worldwide.

Abstract

Migration is the move from one geographic location to another. Residential migration occurs when the household (or person) changes its place of residence by moving from one neighborhood to another within the same locality. Internal migration occurs when the household moves across larger geographically distinct units – such as counties, metropolitan areas, states, or provinces – but remains within the same country. International migration occurs when the household moves across national boundaries.

The study of migration, the movement of workers from one geographic location to another, lies at the core of labor economics because the analysis of labor flows is a central ingredient in any discussion of labor market equilibrium. Workers respond to regional differences in economic outcomes by voting with their feet. These labor flows improve labor market efficiency. This article summarizes the determinants and consequences of both internal migration (labor flows within a given country) and international migration (labor flows across countries).

Migration and Economic Efficiency

The study of migration lies at the core of labor economics because the analysis of labor flows – whether within or across countries – is a central ingredient in any discussion of labor market equilibrium. Workers respond to regional differences in economic outcomes by voting with their feet. These labor flows improve labor market efficiency.

Suppose there are two regional labor markets in a particular country, the North and the South, and that these two markets employ workers of similar skills. Suppose further that the current wage in the North exceeds the wage in the South.

Under some conditions, the wage differential between the two regions will not persist once the economy attains a competitive national equilibrium. After all, the wage differential encourages some Southern workers to pack up and move to the North, where they can earn higher wages and presumably attain a higher level of utility. The flow of Southern workers into the North would raise the Southern wage and depress the Northern wage. If there were free entry and exit of workers in and out of labor markets, the national economy would eventually be characterized by a single wage.

The single wage property of competitive equilibrium has important implications for economic efficiency. The theory of labor demand shows that the wage equals the value of marginal product of labor in a competitive market. As workers move to the region that provides the best opportunities, they eliminate regional wage differentials. Therefore, workers of given skills have the same value of marginal product of labor in all markets. The allocation of workers to firms that equates the value of marginal product across markets is an efficient allocation because it maximizes national income.

To see why a competitive equilibrium is efficient, suppose that a benevolent dictator takes over the economy and that this dictator has the power to dispatch workers across regions. In making allocation decisions, this dictator has one overriding objective: to maximize the country's income. When the dictator first takes over, he sees that the wage in the North exceeds the wage in the South. This wage gap implies that the value of marginal product of labor is greater in the North than in the South.

The dictator picks a worker at random. Where should this worker be allocated? Because the dictator wants to maximize national income, the worker will be sent to the region where he is most productive, the North. In fact, the dictator will keep allocating workers to the Northern region as long as the value of marginal product of labor is greater in the North than in the South. The law of diminishing returns implies that as the dictator forces more and more people to work in the North, the value of marginal product of Northern workers declines. In the end, the dictator will maximize national income only when the value of marginal product of workers is the same in all labor markets.

To easily illustrate this fundamental result, consider the representation in Figure 1. The North (N) is an industrialized region with relatively few workers, while the South (S) has a large population and lags behind the North in economic development. Initially, the wage in the North, W_N, exceeds the wage in the South, W_S.

The two regions have downward sloping labor demand curves that are assumed to have the same slope, but may have different intercepts. The difference between the intercepts measures the economic value of the different infrastructures, with the North's infrastructure allowing any specific worker to have a higher value of marginal product in the North than in the South. Consider a short-run situation where the infrastructure is fixed in each region, so that the height of each labor demand curve is fixed. Finally, assume that all labor is supplied inelastically in each of the regions, with supply curves S_N and S_S.

Figure 1 illustrates the initial labor market equilibrium. Because of the initial supply imbalance and because of the gap in the value of marginal product for any specific worker, the wage in the North is higher than the wage in the South. Income-maximizing workers in the South wish to move to the North to take advantage of the higher wage.

Suppose migration is costless. Workers then move from the low-wage to the high-wage region as long as any wage difference exists, and the flow stops only when the wage in the two

Figure 1 The gains from migration.

regions is equalized at w^*. Each point on the labor demand curve gives the value of marginal product of the last worker hired. As a result, the area under the demand curve gives the total product of all workers hired. The exit of M workers from the South generates a loss in the South's gross domestic product (GDP) equal to the area of the trapezoid C. At the same time, the entry of M workers in the North increases the North's GDP by the size of the area of the trapezoid $A + B$. Note that the South's loss in GDP is also given by the (mirror-image) trapezoid B in the graph illustrating conditions in the North's labor market. The increase in national income, therefore, is given by the triangle A.

In sum, migration and economic efficiency are closely linked in a competitive economy. Through an 'invisible hand,' workers who search selfishly for better opportunities accomplish a goal that no one in the economy had in mind: an efficient allocation of resources.

An Economic Model of Migration

In 1932, Sir John Hicks argued that "differences in net economic advantages, chiefly differences in wages, are the main causes of migration." Practically all modern studies of migration use this hypothesis as the point of departure and view the migration of workers as a type of human capital investment (Sjaastad, 1962). Workers calculate the value of the opportunities available in each of the alternative labor markets, net out the cost of making the move, and choose whichever option maximizes the net present value of lifetime income.

Suppose there are two labor markets where a particular worker can be employed. The worker is currently employed in region i and is considering a move to region j. The worker, who is t years old, earns w_{it} dollars. If he were to move, he would earn w_{jt} dollars. It costs C dollars to move from i to j. These migration costs include the actual expenditures incurred in transporting the worker and his family, as well as the dollar value of the 'psychic cost' – the pain and suffering that inevitably occurs when one moves away from family, neighbors, and social networks.

Like all other human capital investments, migration decisions are guided by the comparison of the present value of lifetime earnings in the alternative opportunities. The net gain to migration is given by:

$$\text{Net Gain} = \sum_{k=t}^{T} \frac{w_{jk} - w_{ik}}{(1+r)^{k-t}} - C \qquad [1]$$

where r is the discount rate and T is the age of retirement. The worker moves if the net gain is positive. A number of empirically testable propositions follow immediately from this framework:

1. An improvement in the economic opportunities available in the destination increases the net gains to migration, and raises the likelihood that the worker moves.
2. An improvement in the economic opportunities at the current location decreases the net gains to migration, and lowers the probability that the worker moves.
3. An increase in migration costs lowers the net gains to migration, and reduces the likelihood of a move.

In sum, migration occurs when there is a good chance that the worker will recoup his human capital investment. As a result, migrants will tend to gravitate from low-income to high-income regions and the larger the income differential between the regions or the cheaper it is to move, the greater the number of migrants.

This framework has been extended to address a slightly different, but equally important, question: *which* persons in the source region are most likely to move? The answer to this question is particularly important for evaluating the impact of migration flows. Suppose that 10% of region i's population chooses to move to region j. The economic impact of this migration on both the source and destination regions will depend on whether the migrants are randomly chosen from the source region's population or are chosen from a particular tail of the skill distribution.

Differences in migration costs across workers help sort out the migrants from the source region's population. Other things being equal, those workers who find it easier to move are the ones who will, in fact, move.

The shape of the income distributions in the two regions will also help sort out the migrants – even if all workers faced the same migration costs (Borjas, 1987; Grogger and Hanson, 2011). Suppose that the skills of workers are portable across the two regions – so that employers value the same types of workers in each of the labor markets. Higher skills typically lead to higher earnings, but the rate of return to skills typically varies across labor markets. Two types of selection may characterize the migrant flow:

1. Positive selection occurs when the migrants have above-average skills. The migrant flow from i to j is positively selected when the destination offers a higher rate of return to skills. The migrants are then drawn from the upper tail of the skill distribution because region i, in a sense, 'taxes' high-skill workers and 'insures' less-skilled workers against poor labor market outcomes.
2. Negative selection occurs when the migrants have below-average skills. The migrant flow is negatively selected when the source region offers a larger payoff to skills. Few skilled workers will then want to move from region i.

In short, as long as regional income differences (net of migration costs) are large enough to induce migration, highly skilled workers will naturally gravitate to those regions where the rate of return to skills is high. In the optimal sorting of workers to regions, highly skilled workers live in regions that offer high rates of return to skills and less-skilled workers live in regions where the rate of return to skills is relatively low.

The simple model in eqn [1] stresses how alternative income streams determine the migration decision for a particular worker. However, it is the alternative streams of utility that determine the worker's decision. After all, the worker cares not only about relative incomes but also about the amenities and disamenities offered by the various regions.

The fact that migration maximizes utility introduces a number of interesting twists into the study of migration decisions. For instance, eqn [1] ignores why there are regional wage differences in the first place, implicitly assuming that the national labor market is in disequilibrium (in the sense that different regions offer different opportunities to the same worker). However, regional wage differences may partly reflect compensating wage differentials that reward workers for the varying set of amenities that different regions offer (Roback, 1982). The wage would then be relatively lower in more pleasant localities. Even though a particular worker might face different wages in different labor markets, the worker's utility would be constant across labor markets. The wage differentials that are the focus of the human capital approach – and that determine the migration decision in eqn [1] – are the ones that persist after the analysis has controlled for regional differences in the value of amenities and disamenities (*see* Wage Differential and Structure).

Internal Migration

Despite problems of comparability, the available data indicate that there is a great deal of internal migration in developed economies. In Ireland and Japan, the 1-year migration rate across local areas (counties in Ireland, prefectures in Japan) is between 2 and 3%, compared to a 1-year migration rate of over 5% in the United States.

Determinants of Internal Migration

A large empirical literature attempts to determine which variables best explain the size and direction of internal migration flows (see the survey in Greenwood, 1997). A few variables have been found to be good predictors in many countries.

Age

Migration is most common among younger workers. The human capital model provides a simple explanation for this pattern. Older workers have a shorter period over which they can collect the returns to the migration investment. The shorter payoff period decreases the net gains to migration, and hence lowers the probability of migration.

Education

Migration is more common among more educated workers. This correlation could arise because highly educated workers may be more efficient at learning about employment opportunities in alternative labor markets, thus reducing migration costs. It is also possible that the geographic region that makes up the relevant labor market is larger for more educated workers. Consider, for example, the labor market faced by college professors. There are few firms in any given city and professors' skills are highly portable across colleges and universities. In effect, college professors sell their skills in a national – or even an international – labor market.

Distance

Greater distances deter migration because greater distances imply larger migration costs. The relationship between distance and migration was an integral part of the 'gravity models' that dominated the literature before the introduction of the human capital framework. The gravity model presumed a (mechanical) direct relationship between migration and the sizes of the destination and origin regions, as well as an inverse relationship between migration and distance.

Other Variables

The evidence linking migration and other variables is more ambiguous. Some studies suggest that persons who are unemployed are more likely to migrate than persons who are not, and that the elasticity of migration with respect to the source region's unemployment rate seems to be stronger for workers who are unemployed (at least in the United States). These studies, however, typically ignore that both employment and migration propensities are endogenously determined. Other studies investigate if the wage differential between the destination and source regions has a positive impact on migration. This direct test of the human capital model requires information on the earnings stream that the worker would face in both the source and the destination regions. As a result, the evidence may be very sensitive to how the selection bias problem is handled. Finally, some studies examine the link between internal migration and differences in social welfare benefits provided by different jurisdictions. Although the

evidence is mixed, recent evidence suggests that 'welfare magnets' attract particular types of person to generous localities (McKinnish, 2007).

Return and Repeat Migration

Workers who have just migrated are very likely to move back to their original location (generating return migration flows), and are also very likely to move onward to still another location (generating repeat migration flows). In the United States, the probability of an interstate migrant returning to the state of origin within a year is about 13%, while the probability of a migrant moving on to yet another state is 15% (DaVanzo, 1983).

Unless economic conditions in the various states change drastically soon after the migration takes place, the high propensity of migrants to move again is not consistent with the simple human capital model summarized in eqn [1]. Prior to the initial migration, the worker's cost–benefit calculation indicated that a move from region i to region j maximized the present value of lifetime earnings (net of migration costs). How can a similar calculation made just a few weeks after the move indicate that returning to i or perhaps moving on to region k maximizes the worker's income?

Two distinct factors can generate return and repeat migration flows. The worker might learn that the initial decision was a mistake. After all, a worker contemplating a move faces an uncertainty about economic conditions in the region of destination. Once he migrates, he might discover that the available opportunities are far worse than what he expected to find. Return and repeat migration flows arise as workers attempt to correct their errors.

Return or repeat migration might also be the career path that maximizes the present value of lifetime earnings in some occupations, even in the absence of any uncertainty about job opportunities in different locations. A brief experience with a particular employer in a different city might provide a 'stepping-stone' to better job opportunities elsewhere in the future. In other words, the temporary stay in region j is but one rung in the career ladder that maximizes lifetime earnings.

Family Migration

The discussion has focused on the behavior of a single worker as he or she compares employment opportunities across regions and chooses the location that maximizes the present value of lifetime earnings. Most migration decisions, however, are not made by single workers, but by families. The migration decision, therefore, should not be based on whether a particular member of the household is better off at the destination than at the origin, but on whether the family as a whole is better off (Mincer, 1978).

Suppose that the household is composed of two persons, a husband and a wife. Let ΔPV_{H} be the change in the present value of the husband's earnings stream if he were to move geographically from region i to region j – net of migration costs. And let ΔPV_{W} be the same change for the wife. If the husband were single, he would migrate if the 'private gains' ΔPV_{H} were positive. If the wife were single, she would migrate if ΔPV_{W} were positive.

The family unit (that is, the husband and the wife) will move if the net gains to the family are positive, or if $\Delta PV_{\mathrm{H}} + \Delta PV_{\mathrm{W}} > 0$. The optimal decision for the family unit is not necessarily the same as what is optimal for a single person. Suppose, for example, that the wife would move on her own if she were single, for she gains from the move (that is, $\Delta PV_{\mathrm{W}} > 0$), but that the husband's loss exceeds her gain (so that $\Delta PV_{\mathrm{H}} + \Delta PV_{\mathrm{W}} < 0$). Hence it is not optimal for the family to move. The wife is, in effect, a 'tied stayer.' She will sacrifice the better employment opportunities available elsewhere because her husband is much better off in their current region of residence.

Similarly, consider the situation where the husband experiences an income loss if he moves on his own (so $\Delta PV_{\mathrm{H}} < 0$). Nevertheless, when he moves as part of a family unit, the wife's gain exceeds the husband's loss (or $\Delta PV_{\mathrm{H}} + \Delta PV_{\mathrm{W}} > 0$), and it is optimal for the family to move. The husband is a 'tied mover.' He follows the wife, even though his employment outlook is better at their current residence.

The analysis suggests that marriage deters migration because a person's private gains may be outweighed by the spouse's losses. The analysis also suggests that migration need not 'pay' for all workers in the family. A comparison of the pre- and postmigration earnings of tied movers would indicate that migration reduced their earnings. The family, however, is better off. Recent studies confirm empirically the importance of viewing migration decisions through a family lens (Costa and Kahn, 2000).

International Migration

There was a resurgence of immigration in the United States and in many other countries at the end of the twentieth century. By the year 2010, about 215 million persons – or roughly 3% of the world's population – resided in a country where they were not born. Nearly 9% of the population in Portugal, 13% in Germany, 14% in Spain, 16% in Austria, and 13% in the United States was foreign born.

Different sets of concerns have motivated economic research on internal and international migration. For the most part, the internal migration literature has examined the determinants of migration – who moves and where. In contrast, the international migration literature has been concerned with the issues that propel the debate over immigration policy. In particular, what is the economic impact of international migration on the host country?

Assimilation and Cohort Effects

The impact of immigration on the host country depends on how the skill distribution of immigrants compares to the skill distribution of the native-born population. A great deal of research attempts to document trends in the skill endowment of the immigrant population, and how that skill endowment adapts to economic and social conditions in the host country through the process of assimilation.

Early studies in this literature used cross-sectional data sets to trace out the age–earnings profiles of immigrants and natives (Chiswick, 1978). A cross-sectional survey allows us to compare the current earnings of newly arrived immigrants (measured as of the time of the survey) with the current

earnings of immigrants who migrated years ago. It was typically found that the earnings of newly arrived immigrant men were substantially lower than the earnings of native-born men. In contrast, immigrants who had been in the host country for two or three decades earned more than native workers did.

These findings were typically interpreted as follows. When immigrants first arrive in their destination, they lack many of the skills valued by host-country employers, including language, educational credentials, and information on what the best-paying jobs are and where they are located. As immigrants learn about the host country, their human capital grows relative to that of natives, and economic assimilation occurs in the sense that immigrant earnings begin to converge to the earnings of natives. Immigrant earnings could eventually surpass native earnings if immigrants are positively selected from the population of the source countries. The cross-sectional evidence thus seemed to indicate that upward mobility was an important aspect of the immigrant experience in many host countries.

This interpretation draws inferences about how the earnings of immigrant workers evolve over time from a single snapshot of the population. Suppose, however, that today's newly arrived immigrants are inherently less skilled than those who arrived 20 years ago. The poor economic performance of recent arrivals may then indicate that the newest immigrants have few skills and poor economic potential and will always have low earnings, while the economic success enjoyed by the earlier arrivals may indicate that the earlier waves were always better skilled and had greater economic potential. Because of these intrinsic differences in skills across immigrant cohorts, one cannot use the current labor market experiences of those who arrived 20 or 30 years ago to forecast the future earnings of newly arrived immigrants (Borjas, 1985).

In short, a cross-sectional survey yields an incorrect picture of the assimilation process if there are skill differentials among immigrant cohorts at the time they entered the host country. These 'cohort effects' can be generated by shifts in immigration policy, by changing economic conditions in the host and source countries, and by selective outmigration of immigrants in the host country.

Many studies, using either longitudinal data or repeated cross-sections, have calculated the rate of economic assimilation and measured the importance of cohort effects in immigrant-receiving countries (see the survey in Borjas, 2014). The findings typically differ across countries. In the United States, the immigrant waves that entered the country in the 1980s and the 1990s were relatively less skilled than the waves that entered in the 1960s and the 1970s. Immigrants in the United States also experience some economic assimilation.

Many of the international differences in the skill endowment of the immigrant population and in the rate of economic assimilation are probably due to differences in immigration or adaptation policies. The existing research, however, has not examined this relationship carefully.

Labor Market Impact of Immigration

The entry of immigrants into a particular labor market should lower the wage of competing workers (workers who have the same types of skills as immigrants), and increase the wage of complementary workers (workers whose skills become more valuable because of immigration). For example, an influx of foreign-born laborers into a particular locality reduces the economic opportunities for laborers who already live in the locality – all laborers now face stiffer competition in the labor market. At the same time, highly skilled natives may gain substantially. They pay less for the services that laborers provide, and natives who hire these laborers can now specialize in producing the goods and services that better suit their skills.

In many host countries, immigrants cluster in a limited number of geographic areas. Many empirical studies exploit this fact to identify the labor market impact of immigration by comparing labor market conditions in 'immigrant cities' with conditions in markets untouched by immigration (Card, 1990; Altonji and Card, 1991). These studies typically correlate some measure of economic outcomes for native workers with a measure of immigrant penetration in the locality and often report a weak 'spatial' correlation. The evidence is often interpreted as indicating that immigration has little impact on the labor market opportunities of the native-born.

The 'short-run' perspective that frames this type of research can be very misleading. Over time, natives who live in the immigrant cities – as well as natives who live in other cities – will likely respond to the entry of immigrants. It is not in the best interest of native-owned firms or native workers to sit still; all natives now have incentives to change their behavior to take advantage of the altered economic landscape.

For instance, native-owned firms see that cities flooded by less-skilled immigrants tend to pay lower wages to laborers. Employers who hire laborers will want to relocate to those cities, and entrepreneurs thinking about starting up new firms will find it more profitable to open them in immigrant areas. The flow of jobs to the immigrant-hit areas helps cushion the adverse effect of immigration on the wage of competing workers in these localities. Similarly, laborers living in areas not directly affected by immigration might have been thinking about moving to the cities penetrated by immigrants *before* the immigrants entered the country. They will now choose to move elsewhere. And some native-born laborers living in the immigrant cities will seek better opportunities elsewhere.

The internal migration of native workers and firms within the host country, in effect, can accomplish what the immigrant flow, with its tendency to cluster in a small number of gateway localities, did not – a 'spreading out' of the additional workers over the entire nation, rather than in just a limited number of localities. A spatial comparison of the employment opportunities of native workers in different localities might show little or no difference because, in the end, immigration affected every city, not just the ones that actually received immigrants.

Because geographic comparisons may not provide valuable information about the economic impact of immigration, many recent studies attempt to measure the effect at the level of the national labor market (Borjas, 2003). These studies identify the impact of immigration by examining how the evolution of average wages for narrowly defined skill groups has been affected by differences in the size of the supply shocks. Specifically, the studies explore how the wage of workers with x years of education and y years of work experience evolves over time, as immigrants increase the supply of that skill group. The descriptive evidence reveals a strong negative correlation

between the wage growth of a specific education–experience skill group and the size of the immigration-induced supply shock in that group. A supply shock that increases the number of workers in a skill group by 10% reduces the wage of that group by around 3–4%.

This approach has also led to a renewed interest in structural methods to estimate the labor market impact of immigration. Specifically, the data allow the analyst to estimate the technological relationships among the skill groups, and then use the resulting elasticities of substitution to simulate the labor market impact of a specific supply shock. The structural approach has one important benefit: it allows the estimation of the impact of immigration on the entire wage structure, including both 'own effects' (i.e., the impact of a supply shock in one skill group on the wage of that group), and 'cross effects' (i.e., the impact of the supply shock on the wage of other groups). The existing evidence, however, suggests that the structural estimates are sensitive to the functional form assumptions made about the production technology in the labor market (Borjas et al., 2012).

The Gains to the Host Country

It is simple to describe how the host country benefits from immigration in the context of the 'textbook model' of a competitive labor market. Consider the standard supply–demand analysis presented in Figure 2. The supply curve of labor is given by S and the demand curve for labor is given by D. For simplicity, suppose that the labor supply curve is inelastic, so that there are N native-born workers. A competitive market equilibrium implies that the N native workers are initially employed at a wage of w_0. The area in the trapezoid $ABN0$ measures the value of national income prior to immigration.

Suppose that immigrants enter the country and that, in the short run, the capital stock remains fixed so that the demand curve does not shift. If we assume that immigrants and natives are perfect substitutes in production, the supply curve shifts to S' and the market wage falls to w_1. National income is now given by the area in the trapezoid $ACM0$. The figure shows that the total wage bill paid to immigrants is given by the area in the rectangle $FCMN$, so that the increase in national income accruing to natives is given by the area in the triangle BCF. This triangle is the *immigration surplus*, and measures the increase in national income that occurs as a result of immigration and that accrues to natives.

Figure 2 The benefits from immigration to the host country.

Why does the host country benefit? Because the market wage equals the productivity of the last immigrant hired. As a result, immigrants increase national income by more than what it costs to employ them. Put differently, all the immigrants hired except for the last one contribute more to the economy than they get paid.

The simulation of this model for the United States suggests that the net benefit from immigration is quite small (Borjas, 1995). If a 10% increase in supply lowers the wage by 3%, the immigration surplus resulting from the fact that approximately 15% of the US workforce is foreign-born is on the order of 0.2% of GDP. This small net gain, however, disguises the fact that there may have substantial wealth transfers from native-born workers to the capitalists who employ the services that immigrants provide.

Immigration alters labor market conditions in both the host and source countries. Moreover, the immigrant population in the host country often makes large financial transfers, or remittances, to family members left in the source country. These remittances can have a substantial impact on economic activity, particularly in developing source countries. The impact of international migration flows on the source countries is only beginning to be studied systematically.

The Global Gains from Open Borders

A number of studies extend the model to explore by how much world GDP would rise if all restrictions that prevent international migration were removed (Hamilton and Whalley, 1984). These studies use the framework developed in Figure 1 to calculate the area of the triangle A when there is 'free' international migration. The estimated gains to world GDP tend to be very large, on the order of tens of trillions of dollars. The simulations also reveal that a very large number of persons (perhaps more than half the world's population) would need to move from the developing to the industrialized economies in order for regional wage differences to be fully equalized (Benhabib and Jovanovic, 2012).

The huge gains from open borders, however, must be contrasted with potential costs, and the nature of these costs has not yet been examined. First, it is not costless to move billions of people across vast distances. Second, most of the global gains result from the fact that the intercept of the labor demand curve in the industrialized region is above the respective intercept in the developing region (as in Figure 1). These different intercepts, however, are the result of economic, institutional, and cultural factors that *endogenously* led to the development of different infrastructures in the two regions, with the Northern infrastructure allowing similarly skilled workers to attain a higher value of marginal product. For immigration to generate substantial global gains, it must be the case that billions of persons can move to the industrialized economies without affecting the underlying factors that led to these infrastructure differentials in the first place.

Abstract

Patterns of migration and aging are reflected in the care and welfare needs of minority ethnic (ME) elders in developed countries, with implications for policy, service design, and care delivery. ME elders have a higher incidence of ill health and poverty, while underusing care services. They are hardnosed in their expectations of care services, identifying dedicated care, communication, and access as paramount. Minority voluntary organizations play a critical role in meeting unmet care needs. Mainstream social care, health, and housing providers and professionals increasingly recognize the specific needs of ME elders, but investment in this area is essential.

Introduction

Human history is a history of migration. Recently, the number of people moving between countries in search of work or fleeing from war or persecution has risen rapidly: between 1960 and 2010 international migration increased by 177%, rising from 77 million to 214 million individuals (OECD, 2012). The aging of populations in large numbers is similarly a recent global phenomenon, which is accelerating. In the first decade of the twenty-first century, the number of people aged 60 or more worldwide reached 810 million (United Nations, 2012). It is estimated that for the first time ever, the number of older people will exceed the number of children worldwide by 2047 (United Nations, 2012). Unprecedented in human history or prehistory, this development is a harbinger of a new world society; and one with huge economic, political, and social implications, including for the cluster of activities, industries, and services associated with care and welfare.

Aging and ethnicity combined is not a new phenomenon. However, its scale and scope are new in view of international migration and shifting global demographic patterns. Recent Western history includes a pattern of inflows of people from slaves, sailors, merchants, and elites from the colonies in the past to migrants, refugees, asylum seekers, settlers, and citizens, at present. What is common to these periods is how economics, politics, and the social and historical location of settlement have determined the patterns of flow of people from one part of the world to another.

This article focuses primarily on migrants who arrived in Europe (Patel, 2003), the United States (Markides and Mindel, 1987), Canada (Koehn, 2009), and Australia (Radermacher et al., 2008) who form minorities, who have settled and contributed in those regions, and who are now living as elders. I refer to this group as 'minority ethnic (ME).' Consideration is given to their experiences of aging, care, and welfare issues such as health, housing, and income; the development and delivery of care, with reference to good practice and implications for social work; and current and future challenges in meeting ME care needs.

ME Elders' Experience of Poverty and Ill Health

For ME elders, there are common experiences and cumulative effects of ethnicity and age, reflected in patterns of settlement and housing, incomes and pensions, social status, education, and health as well as diverse cultural traditions and ethnicities. Although some experiences and consequences of aging are independent of ethnicity, the distinctive experience of ME elders is one of discrimination; and ethnicity is frequently a predictor of that discrimination rather than age. At the same time, people are complex and have several identities, giving rise to multiple and intersectional discrimination, which compound the challenges faced by ME elders – whether these other identities arise from gender, religion, disability, or other sources.

While ME elders are not homogeneous, like elders in the majority population, issues such as health, income, and housing for ME elders have an ethnic face irrespective of their specific backgrounds or identities. For all elders the link between poverty and health is well established. There are patterns of economic and health inequalities that necessitate policies on poverty reduction and tailor-made interventions, including culturally competent health, social care, and housing services (see 'Aging now' in the film *Progressing Policy with Passion*).

Income

The ME aging experiences exhibit a higher incidence of poverty compared to their majority peers. Even in relatively rich countries, such as Finland, the United Kingdom, and Germany in the early 2000s, the percentage of ME elders with incomes of less than €750 per month was 48%, 35%, and 25%, respectively of the total ME populations in each country. Moreover, in each case 40% or more were dependent on social benefits (Minority Elderly Care or MEC Project). These data are taken from the 'MEC Project,' which was instituted and led by myself at Policy Research Institute on Ageing and Ethnicity, involving institutions from 10 European countries (**Table 1** lists the countries) (www.priae.org). The project conducted an in-depth interview-based survey of 3277 minority elders and 901 service providers across these European countries over a 3-year period up to 2005.

In the United Kingdom, ME elders receive lower pensionable incomes than their majority peers (Khan, 2008). ME elder women are likely to be poorer than their peers in the majority, representing a triple jeopardy. Being an older woman is doubly disadvantageous; and being a minority one multiplies the disadvantage further (Patel and Traynor, 2005).

Table 1 Elders' expectations of service-delivery quality in care services, in Europe as a whole and by country

Country	*Main minority ethnic groups surveyed*	*Most important expectation*	*Second most important expectation*
Bosnia/Croatia	Hungarians, Bosniaks, Czechs, Roma	Hygiene and tidiness	Identity appropriate care (religious, gender, ethnic)
Finland	Sami, Russian, Vietnamese	Effective information and care systems	Identity appropriate care (cultural values, ethnic)
France	Algerian, Moroccan, Vietnamese	Effective information and care systems	Identity appropriate care (gender, ethnic)
Germany	Turkish, Italian, German Repatriates	Effective information and care systems	Identity appropriate care (linguistic, ethnic)
Hungary	Roma, German, Croats	Access to care services	Identity appropriate care (gender, ethnic)
Netherlands	Surinamese, Moluccans, Turkish	Effective information and care systems	Access to care services
Spain	Moroccan, Roma, Latin American	Access to care services	Identity appropriate care (gender, ethnic)
Switzerland	Spaniards, Italians, Former Yugoslavia	Access to care services	Identity appropriate care (ethnic)
United Kingdom	African-Caribbean, South Asian, Chinese	Effective information and care systems	Identity appropriate care (religious)
All countries	All, as above	Effective information and care systems	Clear communication

Note: Summary of factor analyses of responses by 3277 elders to an extensive set of Likert-scale questions.
Source: PRIAE MEC Project database (www.priae.org).

The reasons for lower pensionable incomes received by ME elders compared to their counterparts in the majority population are due to factors such as late entry into the labor market (especially if they migrated as adults); lower/differential earnings from lower status and unskilled jobs, conflated by discriminatory behavior by employers; a lower participation in the labor market; lack of knowledge of age related entitlements (e.g., because information is not available in their primary language); or not claiming the full/any amounts (often for cultural reasons). During their working years, ME elders experience at least twice the rate of unemployment than the older majority population, and for longer periods. The nature of the manual jobs that ME elders have occupied affects their income and health in later years. Ill health contributes to early aging, early retirement, and lower life expectancy (Patel, 1990; Haas et al., 2012).

Health

Health and ethnicity are separately – and to some extent jointly – established areas of study in Western countries, but a focus on ME elders and their health is relatively recent. National data limitations on age ethnicity and health have contributed to the lack of investigation of issues related to ethnic health inequalities. In the last decade, however, there has been a growing attention to both the physical and mental health of ME elders across Europe, the United States, Canada, and Australia (Nazroo, 2003; Patel, 2003; Rao et al., 2006; Koehn, 2009; Haas et al., 2012). See 'Mental Health and Physical Active Aging' in films *Dementia Matters Ethnic Concerns; Get Active Today*.

ME elders have multiple and complex health needs. Experience of debilitating long-term illnesses such as heart disease, diabetes, and hypertension are more common than among older majority populations. In addition, there are differences between ethnic groups and by gender: for example, in the United Kingdom, South Asian groups have higher rates of diabetes than the Chinese and are approximately 50% more likely to die prematurely from coronary heart disease than the general population; in Finland, 46% of Vietnamese reported poor health compared to 12% of Russians and 8% of Sami; in Hungary, Roma people have worse overall health than Croats, and Germans, and Roma women suffer greater ill health than Roma men. Across Europe, diabetes and cardiovascular disease are high among some groups (Surinamese in the Netherlands, Asians in the United Kingdom, Moroccans in Spain, Russians in Finland), while for other groups high levels of hypertension, bone disease, and mental health are particular concerns (PRIAE, 2004). Such individual conditions can additionally give rise to multiple complications, unless treated and managed appropriately.

The main reasons for a higher prevalence of ill health among ME elders include: genetics, socioeconomic inequalities, and limited access to health and care services. Factors underlying these reasons, or conflating them, include inappropriate diagnoses (health experts may be unaware of relevant ME issues), discrimination and racism, the type of employment in working years, language and communication difficulties, cultural and faith-based factors (rationalizing dementia as an 'act of God,' for example) and health-related behaviors regarding physical activity, food, and drink.

In some areas of health, ME elders are 'invisible,' or a 'hidden problem,' and so have not been considered in research, practice, or policy until recently. Alzheimer's disease is the most common type of dementia that has been referred to as the 'silent killer' since it is a progressive, degenerative disease of the brain. It cannot be prevented, or cured. Age is a major 'risk factor,' and therefore, dementia is becoming as western societies become older on average. For instance, it is the sixth leading cause of death in the United States. Research into ethnicity and dementia is well advanced in the United States, compared to Europe and Australia; but there is lower level of awareness of Alzheimer's disease among ME families and elders. The necessary information is scarce, including in ME languages; inadequate knowledge and communication also lowers access to services; and cultural preconceptions of how dementia is understood results in late referrals to care professionals, often delayed to a point where ME elders' dementia has considerably worsened (Patel et al., 1998; Jimenez et al., 2013).

Mental health problems also arise from isolation and loneliness, which are features of old age in many societies, particularly those in the West that emphasize privacy and individual fulfillment. ME elders are not immune from loneliness,

multiplied by factors such as poor fluency in the majority language, inadequate communication, ill health (and resultant disabilities), and poverty that socially exclude them from participating in many activities. In such cases, families become the main source of support and comfort, but as with the majority population this is seldom enough (Radermacher et al., 2008).

Housing

> The popular image of a … British family … is a husband, wife and two children. For (an ethnic minority family) the popular image is one of an extended family network, 'families within families', providers of care and social and psychological support. Strangely such virtues are married to a conception of 'overcrowded households'!. (Patel, 1990: p. 30)

These stereotypes were never true, and today, ME elders are far less likely to live in extended family or multigenerational households. As with any person, for ME elders housing is an essential anchor, providing for certain basic needs, as well as giving a sense of location, which is particularly important in later stages of life. In their old age, with increasing illness and poverty, a home where they can age with comfort and support is the least that elders can expect. Suitably adapted housing (including culturally and identity appropriate services) can not only ameliorate a range of health problems for older people, but also with social contact and activities, improve their quality of life. See 'Multicultural housing' in film *Progressing Policy with Passion*.

Meeting the hopes and expectations for appropriate care requires changes in policy and practices. Higher life expectancies, increasing numbers of older people (and hence an expanding market), a societal conversation about autonomy and choice are all resulting in moves toward new and more flexible systems of health and social care in response to majority older people's needs (keeping affordability and costs in mind). Similar moves, haltingly perhaps, but in the right direction, aided by research and other work on ME elders, is also leading planners and developers to provide appropriate housing solutions for ME elders. Examples of minority ethnic housing associations in the United Kingdom include, Ashana House, Great Wall Housing, Unity, Ujama, Sadeh Lok, and Pine Court. In the process, debates about 'separate housing or not' have been defused through successful working multicultural models of housing.

Additionally, there is a continuing discussion of how their families and communities respond to ME 'elder housing' when culturally such schemes are not deemed to be the norm. However, the common long-held view that 'minorities look after themselves' (thus obviating consideration of specialist care and services as ME elders age) is incorrect. Research and active dissemination work with ME age and housing organizations show that elders and families need tailor-made information, examples, and support to better understand, and increase confidence in considering and choosing among housing options in old age when the need arises (Patel and Traynor, 2006; Mahmood et al., 2008).

Encouraging Take-Up of Services

Amid high levels of ill health and poverty, underuse of services by ME elders persists, and needs to be understood. The 10 European country–MEC project revealed a range of explanatory factors, including lack of knowledge, language difficulties, income disparity, inappropriate services (lack of an appropriate cultural mix), discriminatory assumptions, and complex health systems. The responses from all of the countries in the MEC project suggest that professionals and managers/planners have hitherto attributed the underusage of services to the inherent characteristics of the elders themselves, and have paid insufficient regard to institutional characteristics and attitudes, or the services provided.

An organization can do several things to help ME elders overcome barriers and gain access to services. For example, good practice examples in Europe in the MEC research include: community outreach to access information and services; and developing and delivering ethnically sensitive day and residential services.

The Development and Delivery of Elder Care Services

Mainstream Services

There is considerable evidence that ME elders are disadvantaged by limited access to services in social care, health, housing, income, and employment. For example, in gaining access to housing, a ME elder needs to be aware of its availability and the route to access it. However, what if the elder:

- Does not know that such services exist?
- Does not know that she or he may be entitled to them?
- Is presented with a complex system (involving referrals, assessment processes, waiting lists, and various agencies) that is not understood?
- Is not confident she or he meets the eligibility conditions?
- Has to be literate in a variety of ways (e.g., language fluency, form filling, engaging in interviews).

For ME elders the nub of the problem is that language and communication difficulties inhibit acquisition of requisite knowledge, even before it can be used to navigate and access services.

'Do not know, do not hear, do not get' is how one ME elder aptly summarized access issues, for instance, in housing (PRIAE, 2008). Moreover, questions also arise of whether available housing services are appropriate for cultural and other reasons. In some cultural frames, the concept of elders being in a separate home/living independently is a source of embarrassment and discouraged. The idea of seeking external help when problems arise is still regarded by many elders from various ethnic backgrounds, with shame and guilt and a sign of family failure (or, worse, their own). Containment of problems and tolerance of whatever the family circumstances dictate often become the reality for many elders. This is not to say that all ME elders fill this profile. Increasingly, where ME housing provision exists, planning by elders and families of their living independently in their own home – but close enough to the family – is rising, to the satisfaction of both (Patel, 1990, 1999).

Let us suppose that ME elders have managed to navigate the information and culture barriers. For some there may still be discrimination in obtaining housing provision. It is not, therefore, surprising that many who have secured housing see

it as a remarkable achievement rather than an entitlement, especially if it meets their needs regarding language and culture.

The lack of access to appropriate services is amplified by insufficient proactive referral, assessment, treatment, and care of all elders with specific health and social care needs. See 'Voices of minority elders' in the film, *Minority Elders Policy Network*.

For example, a multifaceted and flexible approach is required in caring for people with dementia. Implicit in this approach is the notion that all people with dementia have a right to available care. Various studies show that ME elders with dementia are marginalized from mainstream health and social care methods and approaches (Patel et al., 1998; Jimenez et al., 2013). To alleviate this problem, films and other materials have been produced by minority ethnic groups to educate and train clinicians and social workers, and thereby boost awareness and referrals (see films under 'Health').

Services Offered by ME Voluntary Organizations

There are countless examples of self-help initiatives by ME elder women and men, sometimes with support from professionals, who have created service organizations to help meet ME elders' needs in multicultural contexts. Many aim to combat exclusion and work to counter discrimination and disadvantage through activities, which range from information and support to the provision of tangible day care and residential services. ME voluntary organizations have emerged as a direct response to ME elders' needs. These are meeting key requirements as expressed by ME elders, such as service availability in their own homes; appropriate food, language, religious and spiritual practices; and as bulwarks against prejudice and racism. Such organizations act as 'primary providers' in many contexts rather than as 'complementary providers,' effectively substituting for elements of mainstream health, social care, and housing services (Patel, 1990; PRIAE, 2004; Dominelli, 2008; Williams and Johnson, 2010). Nonetheless, ME organizations' approaches to services provision can be valuable for mainstream organizations because their existence provides role models of multicultural care for mainstream service providers to emulate and build upon.

Toward a Wider Recognition of the 'Specific' Needs of ME Elders

The central idea that ME elders have 'specific' needs has had a troubled journey. For over two decades, the subject has been marginalized under 'special needs'; or has not been considered important on the basis that 'services are open to all.' The MEC Project results show that over time professionals and planners in some countries are recognizing that ME elders have specific needs and that these have to be met. Nevertheless, in several countries in this project barely 50% of professional respondents recognized that ME elders have specific needs and encounter access barriers (France, Finland, Hungary, the Netherlands, and Spain). The United Kingdom and Germany had the highest level of recognition of these issues – over 80% among UK professionals and over 60% in Germany. This result could be attributed to organized responses against racism and discrimination in care and welfare from ME communities working in alliance with majority community professionals. Beyond recognition that specific needs exist, many care professionals across Europe have yet to fully understand the nature and characteristics of ME elders' needs and expectations.

Analysis of the MEC Project survey shows that, as a whole, ME elders' have five key expectations of quality of care services received: effective information and care systems, good communication, full access to services, identity appropriate care, and tangible issues such as hygiene and tidiness (**Table 1**). These mirror the difficulties encountered in mainstream services, as mentioned earlier.

The first expectation, *effective information and care systems*, underscores that for ME elders, care systems and professional, expert staff are paramount; and that full information on diagnoses, treatment, and access should be provided. 'Soft' aspects such as trust and assurance, empathy, and privacy are implicit in this first expectation. Linked to it is that of full access to services (third expectation in the table); and the availability of services in ME elders' own language or presence of an appropriate interpreter is also a priority (second expectation). In a similar vein, the fourth expectation, identity appropriate care, relates to individuals' emotional core, and ultimately their dignity. The fifth expectation includes not just hygiene and tidiness of care facilities, but also the presentation, neatness, and practices of staff. Research in other European countries, North America and elsewhere supports the above findings that 'matter-of-fact,' clinical issues are paramount in ME elders' requirements for good quality care (Miranda et al., 2010; Garroutte et al., 2008).

There are country differences in elders' expectations, partly reflecting the mix of ethnic groups in each country. For example, from the MEC results across Europe, identity appropriate care is normally deemed the second most important aspect in defining good care, but what defines these identities varies: for ME elders in Finland cultural values are to the fore; in Germany it is language; and in the United Kingdom it is religion (**Table 1**). This is not unexpected given that people possess multiple identities. However, variations between countries have policy implications regarding the balance in relevant aspects of service provision. Identity is important, but what constitutes identity differs, context matters, and recognizing diversity is important.

Current and Future Developments

While many countries with ME elders have made considerable progress in the area of aging and ethnicity, the emerging challenge for the care industry and its workforce is not whether there will be a greater number of ethnic elders, but that they are increasingly from many cultures, with different languages and faiths; and with various socioeconomic and health patterns. ME elders today and in the future will have a greater variety of needs, many of which must be reflected in services provided. How policy makers and service providers

can best be informed to determine demand and meet diverse needs appropriately is the issue. Providers need to consider how they can better gear up to meet the increase and mix in demand for services in this context, and how they can ensure that voice, choice, and autonomy are met for individuals from all cultures.

Policy makers are often insufficiently engaged with ME elders, or their organizations, and consequently miss them off the policy radar, considering aging and ethnicity together. This leads to the notion that "in age 'race' is blind; in 'race' age is blind" (PRIAE, 2004: p. 15). However, through targeted efforts by specific organizations, individuals, and professionals, ME elders are now being increasingly considered in policy, care, research, and training, albeit to a variable degree.

The MEC Project reinforced an important policy message: that increasingly in all countries care professionals are recognizing that ME elders have specific needs which are growing, but are often insufficiently catered for. ME voluntary age organizations are an important element of providing for that critical care, but are not the full answer. Unfortunately, policy makers still do not pay sufficient heed to such entities as key resources for supplying tailored services to ME elders.

In the last decade or so, mainstream health, social care, and housing providers have made progress in the recruitment of ME staff, the development of ME elder facilities, information provision, and communication campaigns on a range of health and social care support issues, as well as in consulting ME elders and ME elders' groups on various age related policy issues. However, progress is not uniform. The quality of services can still be categorized as 'patchy, ad hoc, and piecemeal,' particularly in the context of rising demand, previous unmet needs, and growing ME elder populations (PRIAE, 2008; Jacobsen et al., 2011; NSPAC, 2011).

More progress on all these fronts is needed. This can build on the considerable research, policy work, and innovative initiatives to date. Unfortunately, it is not uncommon to hear that not much work exists, that researchers have to start anew. At the same time there are many challenges that need to be met today or in the near future.

First, effective provision of ME-tailored services requires effective staffing. Ethnicity and aging require an engagement with multidimensional issues, some of which are complex and uncomfortable for care staff (Patel, 1995; Sakamoto, 2007; Dominelli, 2008). This is not helped by care staff in social work, and related areas, having to work under pressurized conditions, in highly regulated services giving them little discretion, with declining resources. They often have to decide whether to go for satisfying basic cultural needs (at a physical level) or engaging with elders to forge a deeper understanding, in order to work with various complexities and contingencies that they are not familiar with. Care staff must be supported and strengthened in this regard.

Secondly, progress in the provision of specific care for ME elders is not without challenges. A long-standing view persists that after the current generation, ME elders will be well integrated into society and not need specific services. Such views are sometime linked to anti-multicultural perspectives. While the mainstreaming of some aspects of care; is, or will undoubtedly be the case, research on aging generally shows that as people age their needs and preferences become more culturally or identity pronounced, not less. Services tailored to ME requirements will continue to be necessary. See 'Integration' in the film *My Yorkshire*.

Finally, increasingly, governments are following ideologies of austerity, with wide-ranging effects, including cuts in services. This is not a good time to 'age.' Current austerity measures in many developed countries have hit services targeted at ME elders, directly and indirectly. For example, privatization and the concentration of services provision in selected organizations are having a deleterious effect on smaller ones, including ME voluntary service providers, as funding is cut or redirected. In this age of austerity, disinclination in use of ME organizations by policy makers may be reinforced, to the detriment of service provision to ME elders. Additionally, there is the tendency by politicians and policy makers to conflate ME elder issues with the ongoing farrago on immigration and welfare entitlements. What should be clearly stated is that this is misdirection. ME elders' expectations and rights as citizens fully derive from their contribution to the economies and societies in which they have settled.

The West is diversity rich. An appropriate and resource efficient response to ME elders' aging in the twenty-first century is to invest in services that *work* for minority ethnic elders, be they located with minority or majority service providers. Investment in care and welfare in developed countries today, not least for MEs, is not an option.

Migration History

KJ Bade, Osnabrveck, Germany

© 2015 Elsevier Ltd. All rights reserved.
This article is reproduced from the previous edition, volume 14, pp. 9809–9815, © 2001, Elsevier Ltd., with revisions made by the Editor.

Abstract

As migration history has both a historiographical and a historical dimension this article branches both sides. The first part gives an overview on issues, concepts, and methods of historiographical migration research. The second part sketches the courses of European and worldwide migrations from early modern times up to the present. In historiographical descriptions of migration movements and migrant behavior on the one hand and in the identities assigned to migrants by authorities controlling migration on the other hand, despite the fundamental differences in motivation and aims, problems of description and ascription seem quite similar on both sides.

The term 'migration history' has historiographical and historical dimensions. This article is thus divided into two sections. The first part outlines concepts and methods, focusing on tasks, fields, and problems of interdisciplinary historical migration research. The second section gives some insight into the history of migration itself, based primarily on modern European history. Non-European migration is included where it was linked in some way to European migration.

Historical Migration Research: Issues and Concepts

Motivations, Patterns, Typologies

Migration has always been a constitutive element of the *conditio humana*, as *homo sapiens* spread over the world as *homo migrans*. The history of migration is part of general history and can only be understood in context. As social processes, after all, migration movements are responses to complex economic, ecological, social and cultural, religious, ethnic, and political conditions and challenges. Migration thereby gradually penetrates all spheres of life. Historical migration research branches spaces, cultures, and historical times. Therefore it is necessary for researchers to adopt an interdisciplinary approach. Varying in degree according to the problem at hand, interdisciplinary research strategies cover almost all human sciences in both contemporary, empirical, and historical migration research.

There was and still is a broad variety of reasons for migration. We can, for example, posit economic or social motivations. Within this field, we could then distinguish between subsistence, betterment, or career migration (Tilly, 1978). These types of movements can in turn be distinguished from migrations motivated by religious and political or ethnonationalistic and racial reasons, which also cause flight and forced migrations. These last include the expulsions and forced repatriations in the twentieth century, where the movement of borders across people often caused movements of people across borders.

Of crucial importance for any critical analysis of historical migration trends – and for an insight into the fate of many migrants, often less a matter of choice than of circumstance – is an awareness of the fact that definitions and attributes such as 'emigrant' and 'immigrant,' 'labor migrant,' or 'refugee' and 'asylum seeker' are ascribed classifications. So far, they have often been assigned for administrative or tax purposes or for epistemological scientific reasons – which also depend on specific classification criteria – but these terms in no way describe the generally multiple identities of migrants (Castles and Miller, 1998).

The matter is even more complicated because when migration was controlled and restricted, migrants had to assume the official classification of their status in order to get past immigration officials, often leaving a 'false trace' in official records and statistics. This is one more reason why we have to distinguish between the way migrants classified themselves and the way they were classified, for example, by the state or contemporary researchers.

Spatial Dimensions and Research Concepts

In examining spatial mobility, we have to distinguish between movements in geographical spaces and those in social spaces. Geographically, the scope of historical migration research ranges from the macro-cosmos of international and intercontinental mass movements to the micro-cosmos of interregional or interlocal migrations, and thus also extend from large-scale studies on a highly abstract level to small-scale case studies with larger socio-historical significance. Levels and methods of historical migration research thus range from micro-historical to meso- and macro-historical approaches, including even multilevel theories of migration research, and from individual or group-specific dimensions to quantitative analyses of highly aggregated mass data serving to determine collective behavior during mass movements. On the temporal axis, the field of historical migration research stretches from long-term studies of single migration movements to cross-sectional analyses of the entire, simultaneous migration in one region or beyond its borders (Lucassen and Lucassen, 1997).

The varying approaches by individual disciplines and the various emphases in interdisciplinary approaches lead to different interpretations of migration history. As a social and historical phenomenon, for instance, migration should be seen as a complex process. According to 'classical' historical migration research, this process was often triggered by an increasing propensity to migrate, e.g., in the case of European transatlantic mass emigration in the nineteenth century, and by the consequently more or less gradual mental segregation from the social

context of the home region. In this process, transatlantic migrant networks played an important role. The next phase would be the transformation – often provoked by some external cause – of this propensity into an actual decision to migrate, followed by the act itself. In the case of dense transnational networks resulting from chain migrations, the departure often took place more or less abruptly. The last phase – provided the migration process was not aborted or reversed by remigration – was described as assimilation into the social and cultural context of the immigration region. In the case of large discrepancies in material culture, sociocultural norms, or collective mentalities, assimilation could become a long-term social and cultural process, sometimes even reaching intergenerational dimensions ('second-generation immigrant').

The 'classical' approaches of historical migration research focused on movement in geographical spaces. In the 1990s, however, new approaches emerged which were to focus upon the movement and positioning of migrants in social spaces. This applied especially to meso-level network theories as well as to theories and typologies of transnational social spaces and migrant identities. These new approaches were derived mainly from the social and political sciences (Faist, 1998, 2000; Pries, 1999), dealing with the accelerated development of transnational structures in the economy, in society, and in politics, against the background of rapidly forced globalization. These new approaches in migration research sometimes lead to unproductive claims of exclusivity and needlessly hostile confrontation with the 'classical' approaches of migration research, even though both approaches can be usefully incorporated into complex research concepts (Gerber, 2000).

Tasks of Historical Migration Research

Historical migration research has three main tasks. The first is to investigate migration movements in terms of volume, courses, and structures. The second task is to study the behavioral patterns of migrants with respect to, for example, region, class, group, and gender. The third task is to embed migration movements and the behavioral patterns of migrants into the framework of population, economy, society, and culture of both emigration and immigration areas. This includes the economic, social, and cultural tensions between both sides encouraging migrations as well as the effects of migration on both sides.

Despite such comprehensive tasks and the fact that the movement of peoples rates as one of the most 'moving' moments in history, historical migration research is not an independent discipline. It is, in fact, an interdisciplinary field of research, to which the humanities as well as social and behavioral sciences contribute.

Historical migration research as an interdisciplinary branch is relatively young. Its main disciplinary foci are the historical sciences, including, inter alia, the history of population, economic, social, cultural, and gender history as well as ethnohistory and historical anthropology. They also include the branches of legal and political history analyzing the structure of migration procedures and their repercussions on migration processes. And there are links to mainly empirical disciplines or approaches that can be also applied to historical issues and historiographical approaches (e.g., sociology, social geography, or social psychology).

Migration Movements: Global and European Perspectives

Migration was and still is by no means a uniquely western phenomenon. People in Africa, Asia, and the New World moved for similar reasons as the Europeans. As in Europe, most people moved over short distances, usually remaining within their own region or continent. Nonetheless, there have been several nonwestern diasporas. Between AD 600 and 1500, the Arabs and the Turks expanded into parts of southern Europe and controlled the Balkans between AD 1500 and 1914. The Japanese and Russians colonized Korea and Siberia respectively, and the Chinese created trading communities along the shores of the Indian Ocean (Hoerder, 2001).

We can classify the history of global migrations according to regions, periods, or migration patterns. We shall focus here, by way of example, on the modern history of European migrations, looking first at the non-European references linked to the external migration of Europeans. We know that the most voluminous migration movements outside of Europe were triggered by the process of European expansion and contraction. Many Europeans and non-Europeans met for the first time during the colonial migrations that followed the age of European 'discoveries,' and, for the last time, during postcolonial migrations from the former European colonies back to the 'mother countries.'

Global Dimensions

Some migrations outside of Europe were directly carried out or instigated by Europeans, e.g., the settler migrations from Europe to North America, South America, South Africa, Australia, and New Zealand (totaling about 70 million people); the transatlantic African slave trade (12 million people); and the migration of colonial soldiers and indentured laborers from China, India, Java, and Japan to the colonial labor markets in Asia, Africa, and South America (2.5 million people). In total, the volume of intercontinental migrations directly caused by the European expansion can be estimated at about 100 million migrants, both voluntary and involuntary.

In addition to migratory movements controlled by Europeans, an unknown number of Africans, Asians, and Amerindians moved as an indirect consequence of European expansion. In the New World, the indigenous Amerindian population migrated or was driven to those regions left to them by the intruding Europeans, a fate shared by the indigenous populations in parts of Southern Africa, Australia, and New Zealand. In Asia and Africa, European expansion led to new jobs in textile mills, mining, cash-crop agriculture, railway construction, and the colonial armies, causing large scale, internal labor migrations. From this point on, we shall only mention migration movements directly controlled by the Europeans.

The migrations resulting from the European expansion can be divided into three types of movements and three periods: (1) the migration to the colonial plantations, mines, and railway construction sites between AD 1500 and 1900; (2) the transatlantic mass exodus of Europeans from the mid-nineteenth century until 1914, and their overseas emigration between 1945 and 1960; (3) the colonial and overseas return

migration as well as the non-European labor migration to Western Europe after 1945. We shall briefly outline the first two movements and include the third in the review of developments in Europe (Section European Dimensions).

The first overseas migration movement started around AD 1500, just after the Iberians had discovered the New World. The Amerindian population declined rapidly because of European epidemic diseases and economic exploitation, while the number of Europeans willing to settle in the American colonies was too small to satisfy the demand for labor in the mines and plantations. The Iberians had been faced with a similar labor shortage in the South of their own peninsula and had imported slave labor from sub-Saharan Africa. Some of these slaves were brought to the New World, and soon the Iberians were also transporting slaves directly from West Africa to the New World. The British, French, and Dutch followed suit, and between AD 1500 and 1850, roughly 5 million slaves were brought to Brazil, 5 million to the Caribbean, and 1 million each to Spanish and North America. In three and a half centuries, less than 4 million Europeans migrated to the New World, making it a demographic extension of Africa, rather than Europe (Emmer, 1991).

After AD 1850, humanitarian protests totally suppressed the Atlantic slave trade and won emancipation for all slaves in the New World. However, the demand for tropical labor remained. The recruitment of free African migrants failed and although the number of European migrants rose dramatically after the middle of the nineteenth century, they chose to settle in the more temperate overseas zones. Employers in the tropical world then turned to Asia; and between AD 1850 and 1914 about 2.5 million migrant workers from India, China, Japan, Java, and Polynesia went to work in the coffee fields around Sao Paulo and on islands off the Peruvian coast to dig guano. They also worked on sugar plantations in the Caribbean, Natal, Fiji, Hawaii, and Queensland, in the tobacco fields of Sumatra, on rubber plantations in Indochina, and they even helped to build the railways of East Africa (Indians) and California (Chinese) (Engerman, 1986; Northrup, 1995).

Most of these Asian workers had signed a contract of indenture that granted them free passage in exchange for overseas employment for a fixed period, and entitled them to return home once their contracts expired. The majority did not return, creating ex-Indian communities in South Africa, Fiji, Hawaii, Trinidad, Guyana, and Suriname; ex-Japanese communities in Brazil and Hawaii; and ex-Chinese communities in the Caribbean and Indonesia. Humanitarian protests in the West and nationalist protests in China and India brought some of these migration movements to an end. After World War II, millions of Asian migrants began to cast their sights on the Middle East.

One special chapter in the encounter between the European and non-European world through migration, was marked by the European transatlantic mass exodus from the mid-nineteenth to early twentieth century (Nugent, 1992; Baines, 1995). This exodus was far stronger than the European colonial migrations. Up to the 1830s, the continental migration from central Europe to eastern and southeastern Europe – in contrast to the emigration from England, Ireland, Scotland, and Wales – was much more powerful than transatlantic migration, which had become a mass movement only by the middle of the century.

As a secular social mass movement, transatlantic migration accompanied the shift in Europe from agriculture to industry. It was the transportation revolution that ultimately facilitated the mass exodus. Of the same importance, however, were the transatlantic networks established by migrations of people and exports of goods and capital even prior to the Industrial Age. The mass migration was preceded by the transatlantic movement of colonial labor and settlement migrations of destitute Europeans – men and women – who worked off their passage to the New World in 'indentured servitude' and were eventually rewarded with a small amount of start-up capital or a piece of land (Wokeck, 1999).

Essential factors in the development of transatlantic emigration in the nineteenth century were the liberty to emigrate from the sending countries, the need for immigrants, and their full acceptance in the receiving countries. The advent of the steamship and the expansion of railroad systems on both sides of the Atlantic made cheap passages possible. Chain migrations established transatlantic networks and a dense transatlantic communication. Once underway, the transatlantic mass movement developed a growing internal dynamic up to World War I, after which migration controls and restrictions began to curb the trend.

Up to the late 1880s, the 'classical' sending regions for mass emigration in the nineteenth century – excluding France, which was hardly affected – were the relatively well-developed industrial countries of western, central, and northern Europe. Once employment increased due to industrialization and the economic tensions toward the United States decreased, transatlantic migration from these regions slowed down in the 1890s, except in the case of Great Britain (Ireland). From the 1880s on, however, emigration from the southern, southeastern, and eastern European regions increased all the more, roughly corresponding to the north-to-south and west-to-east rate of industrialization. In the USA, this transatlantic movement soon came to be known as the 'new immigration.'

A gross total of 63 million (including returnees) and a net total of 50–55 million Europeans emigrated overseas from AD 1820 to 1915. The main destinations up to the late nineteenth century were in North America, with the US far ahead of Canada. New Zealand and Australia began to catch up in the 1860s, as did South American countries, which had had mixed populations since the colonial era, from the 1870s. Beginning in the 1880s and 1890s, Argentina and Brazil attracted large numbers of emigrants in the growing wave of migration from southern Europe, especially from Spain and Portugal, causing a fall in the percentage entering the United States – from about 80% prior to 1850, to about 75% from 1851 to 1890, and about 50% from then on.

European overseas emigration reached a climax between 1945 and 1960. Up to the mid-1960s, it still included more people than the immigration to Europe from Turkey, Asia, Africa, and the Caribbean (Münz, 1997: p. 225).

European Dimensions

Europe was really on the move in the nineteenth and twentieth centuries, but also in the Middle Ages and the early modern period. If we could look at spatial mobility from the Middle Ages up to the end of the twentieth century and at the same

time could eliminate reduced traveling times and longer distances due to innovations like the steamship, the railway, and the airplane, we probably would not see a major rise in mobility toward industrial and postindustrial Europe. In the Middle Ages, after all, the majority of the European population, at least for certain parts of their lifetimes, had to be mobile to survive; only a minority stayed at home living off subsistence farming or local employment throughout their lives (Schubert, 1995).

In the early modern period, various groups of European migrants, temporarily or permanently, moved over great distances over land or water. Among other groups there were migrating artists and artisans, architects and technical experts, seasonal or itinerant laborers and migrating tradesmen of fixed abode, travellers, laborers, mercenaries, sailors, and laborers for the maritime and colonial labor markets. There were settlement migrations recruited or invited by state authorities, e.g., the 'Peuplierung' of Prussia, the 'impopulation' of the Donau monarchy, and the colonial settlements in Russia under Katharine II. And there were the movements of religious refugees and expellees, who were often welcomed with open arms for economic reasons by the host authorities. All these long-distance movements were paralleled by an even greater number of short-distance moves between villages and small cities.

The three most relevant large-scale types of migration in modern Europe were: (1) flight and forced migrations in Europe; (2) economically motivated migrations in Europe; and (3) flight, minority, and economically motivated migrations to Europe (Page Moch, 1992; Bade, 2000).

1. Among flight and forced migrations, movements for religious but also for political reasons predominated during the European cultural crisis of the early modern era. In both the late eighteenth and especially in the nineteenth centuries, however, the most common reason for flight and exile was political persecution. Perceived as a threat to the European stability pact negotiated at the Congress of Vienna in 1815, all constitutional reform, national, and social movements were radically suppressed. Revolts and revolutions were crushed, causing a dramatic rise in the numbers of political refugees. The period from AD 1830 to 1848/1849, qualified the nineteenth century as the era of political exile. Still, the number of political refugees was low in comparison to that of new types of refugees, casualties of the epoch of the nation-state. The founding of the nation-states created minorities within national borders, thereby laying the foundations for the flight and forced migrations of the twentieth century, which would go down in history as the 'century of refugees.'

The series of benchmarks of the tragedy of flight and forced migrations in the twentieth century began with World War I, during which millions fled war zones or were deported. During the interwar period, about 1.5 million people fled from Revolutionary and Soviet Russia, while around 5 million were resettled as a result of the great 'population swap' carved out by the new nation-states that had emerged from the ashes of the three multi-ethnic empires. During World War II all this, however, was surpassed by the flight and deportations of 50–60 million people, out of whom 6 million Jews were killed in mass executions or industrialized mass murder in German concentration and extermination camps. Immediately after World War II came the expulsion of about 14 million Germans from the former Eastern territories of the German Reich and from the settlement districts of ethnic Germans in the East. After the era of flight from eastern to central and western Europe during the Cold War, the 'ethnic cleansing' of the interwar period and of World War II, was reenacted in the early 1990s in the expulsions and flight caused by the wars in the former multi-ethnic republic of Yugoslavia.

2. Besides migrant trade – very important up to the expansion of commodity markets in the nineteenth century – labor migrations were the most important among economically motivated movements. They evolved into predominantly agricultural migration systems with fixed circular movements (Lucassen, 1987). These systems were held together by long seasonal migration traditions between regions with virtually inverse requirements: the poor, rural, sending regions did not have enough work or had work at very low wages and had seasonally available surplus labor. The target areas, usually involved in intensive monoculture, offered seasonal work and much higher wages than the sending regions. Apart from agriculture, seasonal construction work in developing cities and their surrounding areas was also attractive.

Out of about 20 European labor migration systems operating at the turn of the eighteenth century, J. Lucassen reconstructed seven larger systems from a far earlier period. In these systems, more than 300 000 labor migrants, men and women, traveled up to 250–300 km at the turn of the century, within and across state borders. The most important of these migrating systems was the 'North Sea system' from the start of the seventeenth to the middle of the nineteenth century. Starting in the Netherlands, it spanned the whole North European coast. Besides supplying seasonal farm labor, the coastal harbors also provided access to the maritime and colonial labor markets of the North Sea system.

During the industrialization process, the magnetic field of migration in North Central Europe underwent a dramatic change in its powers of attraction. The North Sea system was overtaken by the new industrial coal and steel mining centers, especially in the Ruhr area and in Lorraine. In North Central Europe, the fall-off in seasonal agricultural migrations to the Netherlands was followed – up to World War I – by an increase in east-to-west migrations to the German Northeastern territories, with women comprising about 50% of the labor force on the huge East-Elbian estates of Prussia. Poles and Italians formed the main contingents of foreign labor in Germany and France, in the *longue durée* hinting at the large-scale inner-European south-to-north and east-to-west migrations which eventually became the hallmark of the second half of the twentieth century.

The two World Wars suspended transnational mobility in the new migration systems, changed it with the restructuring of the German Northeastern territories after World War I, and brought it to a complete standstill with the loss of the German Eastern territories after World War II. During World War II, labor migrations in Nazi Germany and in German-occupied Europe were largely replaced by the deportation and forced employment of disenfranchised slave laborers, who accounted for most of the 11 million 'displaced persons' (DPs) after World War II.

Only 10 years after a war that Germany had started, Germany and Italy signed the Labor Recruitment Treaty of 1955, paving the way for the future pan-European system of 'guest worker migrations.' Leaving Turkey aside, all the sending regions lay in the northern Mediterranean. Receiving areas were the highly industrialized and economically thriving countries of central, northern, and western Europe up to the first half of the 1970s, when, in the face of projected economic crises, recruitment bans and immigration restrictions were introduced.

Despite the high level of remigration, many labor migrants at that time settled in the host countries and sent for their families to join them. Short-term migrations became long-term ones, ultimately evolving into genuine immigration processes. Since the late 1970s, they have gradually transformed the host countries of 'guest worker migrations' into immigration countries.

In the former colonial nations, particularly in England, France, and the Netherlands, the role of 'guest workers' was first occupied by postcolonial immigrations, which were generally permanent from the outset. During the whole decolonization process, about 7 million people, including remigrating Europeans, migrated from the former European colonies to Europe after World War II. Profound changes took place, when, in the 1980s, the now thriving former south European sending regions of 'guest worker migrations' received increasing intercontinental south-to-north migrations. This ultimately transformed Europe as a whole from an emigration into an immigration continent.

3. The 'new immigrations' to Europe included both intercontinental south-to-north migrations and the new east-to-west migrations since the fall of the Iron Curtain. As in postcolonial migrations, privileged migrations legitimized by historical or cultural links to the host regions were predominant here. This mainly included minorities from the former Soviet Empire and its successor states, such as Armenians, ethnic Germans, and Jews (Bade and Oltmer, 1999; Fassmann and Münz, 2000). Apart from, and often coinciding with, non-European labor migrations to Europe, there were growing global migrations of asylum-seeking refugees in the south-to-north direction since the early 1980s, and, since the fall of the Iron Curtain, there have been increasing migrations in the east-to-west direction also.

Worldwide migration movements have increased in this age of globalization, media, and information networks. Yet, for the most part migrants remained in the surrounding areas of the sending regions and the percentage reaching Europe was still only about 5% at the end of the twentieth century. Nevertheless, horror visions of global mass migrations toward the continent have captured the European imagination, equating migration policy with security and defense policy.

Experts differ in their assessment of the 'migration pressure' from the southern and eastern regions. The key questions are whether it is even directed at Europe, whether it will gradually and inexorably grow, and whether it can be curbed by coordinated – i.e., global, not just European – intervention ('global governance') to control the causes of migration (Nuscheler, 1995; Opitz, 1997). From the entire range of conceivable strategies, Europe up to 2001 has done the least to tackle the causes of involuntary migration in the sending areas, and the most to combat flight migrations to Europe.

With freedom of movement within the European Union, internal 'vulnerability' grew – to use defense policy jargon – due to immigrations from outside the Community. The flip side of opening the borders has therefore been the increased closure of 'Fortress Europe.' Apart from private visits, tourism, and other short-term stays, the European defense system against non-European immigration only admits people welcome for economic, cultural, or other grounds, e.g., highly qualified specialists, scientists, artists, and people who are accepted as members of privileged postcolonial or ethnic minorities or have to be tolerated to some extent because of universalist or human-rights principles (family reunions, refugees, asylum seekers) (Santel, 1995).

In current migration debates and migration policies the tension has increased between self-descriptions and official ascriptions, i.e., between the way migrants perceive themselves and the identities assigned to them by immigration authorities. Migrants must do their best to fit into these assigned identities in order to have a chance of acceptance. Ascriptions, e.g., of 'refugee characteristics,' are the codes of administrative systems controlling and managing migrants' destinies. The decision on who is a 'real' refugee, depends on the fulfillment of these one-sided criteria. What matters most to asylum-seeking refugees is, therefore, often not what has happened to them, but whether their stories fit into the catalog of available ascriptions laid down by the host country. Hence, the approaches of migration policy and migration research to such conceptual problems of migration, may seem quite similar, – despite the fundamental conflict of interest concerning the ascriptions used on both sides (Bade, 2000).

Migration: Motivations

Douglas S Massey, Office of Population Research, Princeton University, Princeton, NJ, USA

Abstract

The motivations for human migration are diverse, but can generally be classified under five basic rubrics: material improvement, risk management, symbolic gratification, social connection, and threat evasion. Most theoretical work in recent decades has focused on motivations connected with material improvement, risk management, and social connection. Less attention has been paid to symbolic gratification and threat evasion. Recent work has suggested the latter motivation may have become increasingly salient in the twenty-first century given global climate change and rising civil violence.

Since our earliest origins as human beings, we have been a migratory species. Around 100 000 years ago, *Homo sapiens* first left East Africa and by around 12 000 years ago had populated all the continents save Antarctica, a uniquely wide and rapid spread in geological terms. Thus, migration is intrinsic to the human condition and geographic movement has always been a key adaptive strategy for human beings (Cavalli-Sforza and Cavalli-Sforza, 1995). The motivations for human migration are diverse, but can generally be classified under five basic rubrics: material improvement, risk management, symbolic gratification, social connection, and threat evasion. Most theoretical work in recent decades has focused on motivations connected with material improvement, risk management, and social connection. Less attention has been paid to symbolic gratification and threat evasion, but the latter has assumed greater importance as a motive for migration in the twenty-first century.

Material Improvement

The desire of people to improve their material circumstances has long been recognized as a key motivation for migration. In prehistoric times, individuals motivated by a desire for material gain moved to gain greater access to natural resources such as water, plants, and game (Massey, 2005). In modern times, they more often move to gain access to economic resources such as earnings, wealth, and education (Sjaastad, 1962). Migration motivated by a desire for material gain is most commonly theorized by neoclassical economics, which views the migratory decision as a cost-benefit analysis whereby rational, utility-maximizing actors balance the gains to be had by working at various geographic locations against the costs of migrating to these places (Todaro and Maruszko, 1987). Individuals maximize utility by moving to the location where the difference between earnings at origin and destination is greatest, net of the costs of migration.

The desire for material gain has also been theorized by the new economics of labor migration, which argues that in addition to maximizing absolute income people often move to increase their incomes relative to others in their communities of reference (Stark, 1991). The new economics framework also argues that people move to overcome missing, failed, or inaccessible markets for capital and credit. A lack of access to capital and credit often represents a barrier to mobility, especially in developing countries. For example, in many poor nations, mortgage markets are rudimentary or nonexistent and credit is difficult or expensive to obtain. In this case, a migrant might be motivated to move to a high-wage country to accumulate savings in order to acquire a home, buy land, start a business, or purchase consumer goods, while other household workers earn subsistence income locally. If the wages abroad are sufficiently high, the migrant might even be able to generate remittances sufficient to support the family while at the same time accumulating savings to finance socioeconomic mobility.

Risk Management

Whether motivated by a desire to maximize expected earnings or to finance purchases in the absence of working markets for capital or credit, the underlying motivation is one of material improvement, a core human motivation (Fiske, 2003). Although a desire for material gain is a core motive for individual action, human beings are also motivated by a strong desire to minimize losses and protect against risk. Psychologically, human beings experience much more pain from a material loss than pleasure from an equivalent material gain, a principle known as loss aversion (Tversky and Kahneman, 1991). Many developing nations lack well-developed insurance markets or government substitutes (unemployment or health insurance schemes). Under these circumstances, actors may employ migration as a means to self-insure against potential losses, and this motivation has also been theorized under the New Economics of Labor Migration (Stark, 1991).

Consider a household that is worried about local economic volatility. Such a household might act strategically to minimize risks to income by diversifying its labor portfolio, sending one member to work somewhere else in the country and another to work at a foreign destination while family members at home work in local labor markets or manage household assets or business enterprises. If conditions deteriorate locally to cause a drop in subsistence or income (because of a drought, recession, or plant closing), the shortfall can be buffered by money remitted by family members employed elsewhere. Sending out different members to work in geographically distinct labor

markets provides 'insurance' in the absence of effective markets or government programs, enabling households to rely on alternative income streams during local downturns. This strategy is feasible as long as economic conditions at origin and destination are not strongly and positively correlated (Massey et al., 1993).

Symbolic Gratification

In addition to moving in order to gain access to material resources, increase relative income, accumulate funds in the absence of capital and credit markets, and hedge against potential losses to income, people also move for purposes of symbolic gratification – to gain status, prestige, and esteem, which are also core human motivations (Fiske, 2003). A college professor may decide to move to another university to accept a named chair, for example, even if the salary remains constant or declines somewhat. Rural residents may be attracted by the bright lights and stimulating activities of a big city, which offers them the chance to become more 'cultured' and 'sophisticated.' Denizens of provincial cities may even be willing to accept a decline in income if they are able to gain access to the prestige and pleasures of the metropolis. Although the economic model of utility maximization can be applied to explain movement for symbolic gains, such motivations have also been treated by sociological theories of cultural capital, which point out that intangible resources such as status, prestige, and esteem are not only valuable motivators in themselves, but also constitute important resources than can be used to advance one's position in society (Bourdieu, 1986).

Social Connection

Human beings are also motivated to affiliate and interact with other people for the exchange of emotional resources such as liking, companionship, love, and sex, as well as to act collectively to achieve instrumental ends (Massey, 2005). *Homo sapiens* has always been a social species and individuals cannot survive, prosper, or reproduce outside of social groups. As a result, human actors are psychologically disposed to maintain and seek out social connections with others (Fiske, 2003). Throughout history, human beings have migrated to get married and married couples separated by migration have been strongly motivated to reunite, either through the return migration of the absent spouse or emigration of the trailing spouse. Such motivation may also be theorized by the neoclassical model of utility maximization, but most work on the social process of migration has been done under the rubric of social capital theory (Massey, 1990; Massey and Espinosa, 1997).

Because individuals are always socially connected to others – through networks defined by kinship, friendship, and acquaintance – migration not only motivates people to migrate for purposes of family reunification, but also confers instrumental value on ties to current or former migrants with experience in high-opportunity destinations (Palloni et al., 2001). The wife of a male migrant may seek to migrate simply to reunite with her husband, but she may also aspire to gain access to greater opportunities for employment and higher wages at the place of destination, or to overcome the patriarchal constraints of rural life (Hondagneu-Sotelo, 1994). Moreover, even if people do not wish to associate with a particular migrant, siblings, cousins, in-laws, and friends, they may be motivated to draw upon their tie to a migrant in order to facilitate migration for their own economic ends, whatever their feelings about family reunification (Massey and Sánchez, 2010). Likewise, a working migrant may learn of economic mobility opportunities at the place of destination, or be asked by a boss to find someone to fill a specific job, and then turn to his social network to fill the position by recruiting someone from his or her sending community (Hagan, 1994; Bashi, 2007).

In short, having a social connection to a migrant reduces the costs and risks of migration so that migratory behavior tends to spread rapidly through social networks, yielding a process known as cumulative causation (Massey, 1990). If someone wishes to migrate from a small Mexican town to the United States without authorization, the prospect is daunting if no one from the community has ever crossed the border before. In the absence of information or experience, undocumented border crossing can be a costly and risky proposition. Once someone from the community has migrated, however, everyone socially connected to that migrant acquires something quite valuable: a tie to someone who knows how to cross the border, find a job, and get by in the United States.

Depending on the closeness of the tie and the social obligations it implies, the migrant may provide information, offer job leads, recommend reliable border smugglers, finance the trip, accompany the person across the border, or offer food and lodging upon arrival. Whatever the specific set of services, the potential costs and risks of migration are reduced for those connected to a migrant, yielding valuable social capital, and some of these connections take advantage of their connection to migrate themselves, which expands the set of people with ties to a migrant, inducing still more to migrate, yielding a self-perpetuating migration chain to promote cumulative causation by reducing the costs and risks of migration from an ever expanding set of people (Massey and Zenteno, 1999).

Threat Evasion

The final motive for migration is the desire to escape an immediate threat to emotional or physical well-being, such as civil violence, family violence, crime, war, natural disasters, political upheaval, or catastrophic economic transformations, events that often produce a stream of out-migrants whose mobility is motivated by well-founded and acute fears for their immediate well-being. They perceive a tangible current or impending risk and move rapidly to escape it, usually but not always by proceeding to the nearest and most accessible safe haven (Kunz, 1973). If they remain within their home nation, they become internally displaced persons and if they cross an international border they become refugees or asylees. Although one might apply neoclassical economics to conceptualize refuge migration as

an exercise in utility maximization, the decision to migrate under threat is more primal than rational and analyses of refugee movements are generally been considered theoretically more in terms of classificatory schemes and conceptual typologies based on the nature of the threat, the form of displacement, and the context of reception (Kunz, 1981; Portes and Rumbaut, 2006).

All migrants are self-selected to some degree, but how refugee migrants are selected depends critically on the social, economic, and political circumstances of their departure, arrival, and prospects for return. Those fleeing an acute event such as a hurricane, an earthquake, or the sudden eruption of military hostilities are generally the least selected. In the most severe cases, everyone who is able moves and only the infirm, feeble, and abjectly impoverished are left behind. Political upheavals, crime, civil violence, and economic catastrophes are generally selective on the basis of traits such as class, political affiliation, ethnicity, and religion. It is difficult, however, to make a priori predictions about political selectivity without a more precise knowledge of the nature of the threat and the timing of its expression. For example, a left-wing revolution might produce the exodus of the property-owning elite (as in Cuba), whereas a right-wing crackdown might spur the departure of the poor (as in Guatemala).

Whatever the original nature of the selection, the incentive to integrate into the receiving society varies systematically with the prospects for return. When people believe that returning home is unlikely or impossible, they have a strong incentive to invest in social integration and economic mobility at the place of destination (Chiswick, 1979). If they believe return is imminent or likely in the short to medium term, they have less incentive to adapt to their new circumstances. If the diaspora proves to be prolonged and not resolved in either direction – settlement or return – refugees may languish in marginalization and poverty for many years or even generations, segregated from the host society but unable to return to their place of origin (Haddad, 2008).

Climate Change

Natural disasters, wars, and revolutions have occurred commonly throughout human history to displace people from their homelands and will no doubt continue to do so in the future. More recently, structural transformations of the economy during shifts from agrarian to industrial or industrial to postindustrial modes of production have long been known to displace people from traditional livelihoods and turn them into migrants (Massey, 1988; Sassen, 1988). In recent years, however, researchers have begun to pay closer attention to two potential drivers of migration that are beginning to appear to be endemic to the twenty-first century: climate change and civil violence.

The term 'environmental refugees' was introduced by El-Hinnawi (1985) to describe people forced to leave their place of origin, either temporarily or permanently, because of environmental disruptions triggered by human or natural events. Suhrke (1994) identified desertification, land degradation, deforestation, and rising sea levels as the most important forms of environmental change leading to out-migration, whereas Hugo (2008) lists environmental disasters, environmental degradation, climate change, and disruptions from large-scale human projects as the principal causes. Jacobson (1988) argues that environmental refugees constitute the single largest class of displaced persons in the world today. Myers and Kent (1995) estimate that some 25 million people were environmental refugees in the mid-1990s. Black (2001), however, questions the very concept and suggests that counts of environmental refugees are wildly inflated. Whatever the number of such refugees, Afifi and Warner (2008) found a positive association between the size of migration flows between 172 countries and measures of overfishing, desertification, water scarcity, soil salinization, deforestation, air pollution, soil erosion, and soil pollution within nations. Thus, migration indeed appears to be one response to environmental change.

Most studies rely on country-specific data rather than cross-national statistical analyses. In their study of migration in Guatemala and Sudan, for example, Bilsborrow and DeLargy (1991) found that a decline in land productivity fostered rural out-migration, whereas Hitztaler (2004) found that resource-poor villages in Russia's Kamchatka region displayed greater rates of out-migration than those with stable resource bases. Similarly, Massey et al. (2010) found that short-distance moves in Nepal were predicted by decreasing access to firewood, declines in agricultural productivity, and decreases in land cover. Bohra-Mishra and Massey (2011a) likewise found significant effects of population pressure, deforestation, and agricultural productivity on the likelihood of local mobility, but found little evidence that environmental deterioration promoted long-distance migration. Estimates derived by Feng et al. (2010), however, uncovered a strong relationship between declining crop yields and out-migration to the United States; and Munshi (2003) documented a significant connection between the scarcity of rainfall and US migration, a connection also observed by Nawrotzki et al. (2012).

Civil Violence

In an era of global climate change, therefore, environmental disruptions clearly carry the potential to promote movement, very clearly over shorter distances but also possibly over longer distances and even internationally. In addition to environmental change, another potential threat common to the contemporary world is civil violence emanating from diverse sources, including crime, political terrorism, narcoterrorism, guerilla insurgencies, revolutions, and state-sponsored repression; and as with environmental change, aggregate-level studies generally uncover a strong connection between such violence and out-migration.

Shellman and Stewart (2007) found, for example, that Haitian emigration to the United States was strongly correlated with surges in political violence, holding economic conditions constant. Morrison (1993) found similar results in Guatemala, as did Morrison and Lafaurie (1994) in Colombia. Jones (1989), however, found the effect of violence on migration was mainly indirect, with conflict producing local economic dislocations that, in turn, led to emigration. Morrison and May (1994) also found that conflict-related economic turmoil was more important than

violence in predicting internal migration within Guatemala, but Schultz (1971) showed that the effect of violence on rural–urban migration in Guatemala was small compared with the effects of socioeconomic and demographic factors.

In addition to these aggregate level studies, a growing number of investigators have examined the connection between violence and individual and household decisions to migrate. In their survey of displaced and nondisplaced persons in Colombia in 2000, for example, both Engel and Ibañez (2007) and Ibáñez and Vélez (2008) found that the threat of violence and the presence of paramilitary and guerilla groups were strongly associated with the likelihood of out-migration. Lundquist and Massey (2005) likewise found that the probability of leaving Nicaragua for the United States was strongly predicted by the intensity of the American Contra Intervention. In Mexico and Costa Rica, Alvarado and Massey (2010), however, found that the effects of lethal violence were small and generally associated with a lower probability of migration to the United States. In their study of Nepal, Bohra-Mishra and Massey (2011b) found that civil violence had nonlinear effects on migration, such that low to moderate levels of violence reduced the likelihood of movement, whereas high levels increased the probability of migration. The effects of violence were confined to local and within-country moves, however, and did not affect the likelihood of emigration from Nepal.

Conclusion

At this point, four of the five general categories of migrant motivations have been well-theorized. Material improvement is covered by neoclassical economics and the new economics of labor migration, risk management is theorized by the new economics of labor migration, symbolic gratification by cultural capital theory, and social connection by social capital theory. These reasons for migration all reflect core human motivations that psychologists have identified as intrinsic to the human condition (Fiske, 2003). Although threat evasion has not received systematic theoretical treatment to the same degree, self-preservation is clearly a fundamental human motivation and recent research has identified environmental change and civil violence as two potentially important drives of migration in the twenty-first century.

To date, most studies have considered climate change and violence as two independent threats, each of which might potentially contribute to the flow of migrants around the world. Recent work suggests, however, that climate change and civil violence are, in fact, causally interrelated. Indeed, Hsiang et al. (2011) show that outbursts of civil violence are closely tied to variations in the El Niño Southern Oscillation (ENSO). They found the probability of a civil conflict erupting doubles during El Niño versus La Niña years, and that the ENSO may have been behind 21% of all civil conflicts between 1950 and 2005. Given the potential of climate change to influence the frequency and severity of weather events such as El Niño, climate change not only has the potential to generate migration directly through displacement but also indirectly by triggering civil conflicts in affected areas throughout the world.

Abstract

This article provides an outline of historical research on emigration from Europe to the New World in the century from 1850. It focuses first on the determinants of the volume and composition of emigration. Second, it examines the assimilation of immigrants and their integration in host country labor markets. The third topic is the rise of restrictive immigration policies and their role in the ending of mass emigration.

Introduction

International migration has been a key element in the development of the Western world since the industrial revolution. Its most profound influence has been on the peopling of the continents of North and South America and Australasia with emigrants of European stock and their descendants. Much of the discussion has focused on what might be called 'the age of mass migration,' from the middle of the nineteenth century to World War I. This was a period of relatively free migration that ended with the spread of immigration controls. Three sets of questions emerge from this experience. One is who migrated, when, and above all, what motivated migration. Another is how immigrants fared in the host country labor market, how their presence was felt by nonimmigrant workers and what were the broader effects on living standards and income distribution. Finally there is the issue of whether, and if so how, these evolving trends led to an immigration policy backlash.

Patterns of Migration

Early settlements of Europeans were progressively established in different parts of the New World from the sixteenth to the eighteenth century. In the century following 1820 about 55 million Europeans set sail for these resource-abundant and labor-scarce destinations and about three-fifths of them went to the United States. Earlier migration had been a trickle by comparison. Some of the early migrants were pioneer settlers seeking to establish new communities free from the religious or political persecution they faced in Europe. There were also streams of convicts and indentured servants sent to work on frontier farms and plantations. These were rapidly overtaken by the mounting numbers of free migrants but it was not until the middle of the nineteenth century that mass migration can really be said to have taken hold. Annual emigration rose from about 300 000 in the 1850s to the 1870s, climbing steeply thereafter to exceed a million at the turn of the century (Figure 1).

The emigrants in 1900 were rather different from those in 1800. Early nineteenth-century migrant streams were often led by farmers and artisans from rural areas traveling in family groups, intending to acquire land and settle permanently at the New World's frontier. In the late-nineteenth century, while many still had rural roots, the emigrants from any given country were increasingly drawn from urban areas and from nonagricultural occupations. About two-thirds were men and the overwhelmingly majority traveled as single individuals rather than in family groups. Of migrants to the United States between 1868 and 1910, 76% were between the ages of 15 and 40 years. While the young and single might be regarded as inherently more adventurous and more mobile, these characteristics also reflect a deeper economic calculus. By emigrating

Figure 1 Emigration from Europe, 1846–1924 (5-year averages). Source: Kirk, D., 1946. Europe's Population in the Interwar Years. Princeton University Press, Princeton, p. 297.

as young adults they were able to reap the gains over most of their working lives. By moving as individuals, they were able to minimize the costs of the move, including earnings foregone during passage and job search. And since the emigrants were typically unskilled, they also had little country- or technology-specific human capital invested and hence stood to lose few of the rents from such acquired skills (except language). Finally, these young adults had the smallest commitment to family and assets at home (Hatton and Williamson, 1998: p. 11–12).

As mass emigration mounted so the composition by country of origin changed. In the middle decades of the nineteenth century, the emigrants came from north-western Europe, chiefly from Britain, Ireland, Germany, and the Scandinavian countries. But as **Figure 1** shows, the great surge in migration after 1880 was dominated by the rise in emigration from the countries of southern and Eastern Europe. Notable among these so-called 'new emigrant' countries were Italy, Spain, Austria-Hungary, and Russia. Statistics such as these hide the enormous variations in *rates* of emigration (per thousand of the source population). The highest was from Ireland with an average emigration rate of 13 per 1000 per annum between 1850 and 1913. Countries such as Sweden and Norway had rates approaching five per 1000 from 1870 to 1913 while the rates for Germany and Belgium were under two per 1000 and those for France were very small. Furthermore, the long run trends in emigration differed widely: from the 1880s rates of emigration declined sharply in Ireland, Germany and Norway while they underwent dramatic increase in Southern and Eastern Europe (Hatton and Williamson, 1998: p. 33).

The Determinants of Emigration

Various hypotheses have been offered to explain variations in emigration across time and place, drawing on perspectives from economics, sociology, demography and geography (Lowell, 1987: Ch. 2). One important fact that such theories must explain is that, during the course of modern economic growth in Europe, national emigration rates often increased, slowly at first from very low levels, rising more steeply to a peak, and then gradually falling. A one factor is rapid population growth, producing large cohorts of young adults whose opportunities to inherit smallholdings or to enter into family businesses were limited. Analysis of cross-country trends in emigration across Europe in the late nineteenth century finds strong evidence of these demographic effects (Hatton and Williamson, 1998: p. 43). There is also some evidence that the more urban the country, the higher was emigration – supporting the notion of greater mobility among urban populations.

Clearly, economic incentives were (and are) a key determinant of migration: average unskilled wage rates in 12 (western) European countries were barely more than half those in the New World (weighted by proportion of emigrants). Wage ratios were an important determinant of emigration rates. On average an increase in the New World real wage by 10% relative to that in Europe generated a rise in the emigration rate of 1.3 per 1000 (Hatton and Williamson, 1998: p. 43). But real wage ratios alone cannot explain why poor countries often had low emigration rates and why emigration often increased as development took place.

Other influences must also be taken into account. One is that many potential migrants were too poor to emigrate. As countries and regions industrialized, and as incomes rose, a larger share of potential migrants could afford to save up sufficient resources to finance the move and hence the number of emigrants increased. Thus in its early stages, increases in emigration could be positively associated with an increase in wage rates at home (even though this narrowed the foreign/home wage gap). As a result, European countries exhibited a long cycle of emigration with and upswing flowed by a downswing, although for many the cycle was not complete by 1913 (Hatton and Williamson, 1998: pp. 48–51).

Persistence and Volatility in Migration

Much of the literature has focused on migrant networks as the key element in determining mass migration. These have both social and economic dimensions. Once established, migration streams perpetuated themselves as previous migrants provided new migrants with prepaid tickets for the passage, food and shelter on arrival, and used their existing networks to help gain access to job opportunities. This 'friends and relatives effect' proved to be a very powerful force in the late-nineteenth century. Evidence from the United States immigration records suggests that as many as 90% of arrivals were traveling to meet a friend or relative who had previously emigrated. Econometric estimates indicate that for each 1000 migrants from a particular country, the friends and relatives effect 'pulled' between 20 and 100 further migrants each year, even when other factors such as relative wages are taken into account. Thus the larger the stock of previous emigrants, the greater would be the flow, and that flow would in turn lead to further flows.

Not only did the friends and relatives effect reduce the costs and uncertainties of migration to the prospective migrant, it also eased the poverty trap. This helps to explain different emigration patterns from countries at similar levels of development. In Ireland, the Great Famine effectively ejected a million migrants who formed a substantial migrant stock, particularly in the United States. Thus, after mid-century even the poorest Irish migrant would have benefited from the assistance of previous emigrants, so emigration depended less on the migrant's own resources and more on the potential gains (Hatton and Williamson, 2005: p. 65). As a result, Irish emigration declined as conditions in Ireland gradually improved. By contrast, in Italy, which had few emigrants before 1870 the poverty constraint was more important and hence emigration increased as the economy developed.

Superimposed on the long run trends in migration streams were sharp year-to-year fluctuations. Gross emigration sometimes fell by as much as half, only to recover a few years later. The literature on annual movements in emigration suggests that business cycle conditions, especially in the destination country, were the key influence and that other influences (such as wages) were relatively unimportant. This has been interpreted to mean that migrants were driven by the 'pull' effects of opportunities in the New World, rather than the 'push' effects of conditions at home. However, careful analysis shows that a model in which both the wage and the probability of employment matter, both at home and abroad can explain time series movements in

emigration reasonably well (Hatton, 1995; Hatton, and Williamson, 1998: Ch. 4). The proportionately larger effect of unemployment, particularly in the destination, reflects risk aversion on the part of potential migrants. The year-to-year volatility of migration can also be interpreted as reflecting the option value of waiting. Thus, even though it may be worthwhile to emigrate now, it may be better still to wait until conditions in the receiving country have improved.

Destination Choice and Return Migration

In the past, emigration streams from a given country were often dominated by one destination, for example, Scandinavian emigrants went almost exclusively to the United States. Consequently, choice among alternative destinations is less well-understood. Choice of location *within* a receiving country is associated with measures of regional income, as might have been expected, and especially with the stock of previous migrants to that state/region. But choice among countries involves additional factors such as cultural and linguistic affinity with the country of origin. Thus emigrants from Italy, Spain, and Portugal revealed much stronger preferences for South American countries such as Argentina and Brazil than did other European emigrants. Given these affinities and the pulling power of previous migrants, these streams persisted in spite of the income advantage of going instead to the United States. However, when new immigrant streams arose, such as that from southern Italy at the turn of the century economic advantage carried more weight. Thus migrants from the north of Italy continued to favor South America over North America (despite their urban backgrounds), while the rural southern Italians migrated in increasing numbers to the urban United States.

Although most migrants were permanent settlers, there were mounting flows of return migrants. By the end of the century, about one-third of European migrants to the United States were returning, usually after a few years, and even this may be an underestimate. Increasing destination wages relative to transport costs and falling voyage times contributed to the trend. But the upward trend in return migration owes most to the changing country composition of emigrants – particularly, the growing share from southern Europe. Many of these emigrants intended to return home and use their accumulated savings to establish families, and often to start farms or businesses. In such cases, the outward flows were more male dominated than where permanent settlement was the goal (Hatton and Williamson, 2005: p. 80). While return migration strategies are not well understood one thing is clear: differences in rates of return migration are associated more with the country of origin than with the country of destination. Thus, the high rates of return migration among southern Europeans at the turn of the century applied equally to those emigrating initially to North America and to South America.

Immigrant Assimilation

It has often been argued that immigrants faced discrimination and prejudice – factors that placed them under social and economic disadvantages and which may have made migration less attractive or encouraged return migration. The US Immigration Commission, which reported in 1911 argued that immigrants themselves, particularly the 'new immigrants' from southern and eastern Europe, were unable or unwilling to integrate into American society and that they lacked the skills and motivation to be successful in the labor market. Instead they crowded into ghettos and into unskilled occupations with little hope of upward mobility. Revisionist writers have argued instead that immigrant communities were not backward looking and isolationist. Rather, they provided a means though which immigrants could maintain their ethnic identity and benefit from social support networks at the same time as gaining access to the means of economic advancement (Bodnar, 1985).

A key issue is whether immigrants did suffer economic disadvantage and whether they caught up with the native born as they acquired knowledge, skills, and experience in the American labor market. The literature on immigrant earnings in the postwar period finds that, soon after arrival, immigrants suffer a significant wage disadvantage relative to the native born but that the difference erodes with time at the destination. Analysis for immigrants at the turn of the century indicates that (contrary to an older view) a similar pattern can be found among immigrants who arrived in adults in the United States around the turn of the century (Hatton and Williamson, 1998: Ch. 7). Those who arrived as children suffered little or no disadvantage and second-generation immigrants often had higher earnings than the native born. While the 'new immigrants' faced some economic disadvantages, much of this can be associated with limited education and English language proficiency – disadvantages that diminished over time. It is worth noting that this initial disadvantage was much less than that faced by immigrants to the United States from the developing world in the years after 1970 (Hatton, 2000).

A related issue is whether immigrants were among the best and the brightest from the source country as has often been assumed. That was undoubtedly true of the pioneer migrants but as mass migration gained momentum, immigrants from a given country became less skilled and educated. Those moving though migrant networks often needed less enterprise and initiative than those who went before. One recent study compares Norwegian male emigrants to the United States from 1865 to 1900 with the brothers that they left behind. The evidence suggests that, had they stayed at home, these emigrants would have attained lower occupational rank than their peers. On this measure at least the migrants were not necessarily the brightest and the best (Abramitsky et al., 2012). Across a range of source counties, the evidence suggests that the higher were the source country returns to education the less likely the more able and educated would emigrate (Baten and Stolz, 2012).

The Labor Market Impact of Immigration

The effect of mass immigration and labor market competition has been a contentious issue, in the past as in the present. A few studies have found that the wages of operatives grew more slowly in cities and regions with the highest rates of immigration (Goldin, 1994). But such effects were ameliorated by mobility, both by immigrants and nonimmigrants across locations, and especially with the expansion into lightly settled areas. Although immigrants often clustered in gateway cities and

other communities, the economy-wide effects of immigration were not easily observed by comparisons across localities.

A number of studies have estimates the labor market effects of immigration using general equilibrium models for the economy as a whole. These are stylized frameworks but they do allow the assessment of a wide variety of direct and indirect effects. One such exercise suggests that, in the absence of immigration from 1870 onward, US real wages would have been 34% higher in 1910 than they actually were (Hatton and Williamson, 1998: p. 212). For Argentina, where the inflow was even larger relative to the population, a different study finds that wages in 1914 would have been 25% higher in the absence of mass immigration after 1870 (Taylor, 1997).

However, such results depend on the counterfactual assumptions upon which such models are based. The most important of these is the international flow of capital. In the era up to 1914, capital flowed from the Old World to the New and especially to those countries that were absorbing immigrants. This helped to boost investment in infrastructure and in a wide range of other enterprises, which in turn prevented a decline in the ratio of capital to labor, and consequently slower growth in productivity and wages that might otherwise have occurred. If capital followed labor to the New World in search of high return then in the absence of mass migration much less capital would have been transferred. As a result, wages would have increased by less in the absence of immigration than in a scenario that does not incorporate the responsiveness of capital flows. To take one example, the effect of immigration to the United States on American wages would fall to 9%, if the responsiveness of capital is taken into account.

Real Wages at Home and Economic Convergence

For European countries, the effects of emigration were largely the opposite; labor supply grew less rapidly than otherwise. Emigration left a less dramatic imprint on population and society in Europe than immigration did in the New World. And it must be placed against a background of industrialization, urbanization, and the demographic transition. Nevertheless, the effects were not negligible. Estimates for several European countries, based on using the general equilibrium framework, suggest that wages would have been lower in 1913 by around to 10% in the absence of emigration. In the UK, unskilled wages would have been 12% lower by 1910 in the absence of emigration from 1870. But if capital outflows had diminished in response then the effect would have been only half as large.

Two implications follow from these economy-wide effects. One is that migration was a force for convergence in real wages and living standards within the so-called Atlantic economy. The available estimates show that in 1870 real wages in the New World were 96% higher than those of the Old World. In the ensuing 40 years that gap narrowed to around 79%. Some of this was due to the transfer of population and labor brought about by half a century of mass migration. One estimate suggests that in its absence the gap between New World and Old World wages would have increased; there would have been divergence rather than convergence (Taylor and Williamson, 1997: p. 40).

The second implication is the contrasting effects on income distribution. As the settler economies became more populated, land prices and rents increased, and combined with the pressure on wages, this caused their income distributions to widen. By contrast, in Europe, emigration tended to promote greater equality as wages rose and the rents and land prices stagnated. This process was enhanced by the ongoing trend of globalization in international trade, which like international migration, was underpinned by falling transport costs. In those European countries that responded by protecting their agricultural sectors with tariffs to blunt the effects of the so-called grain invasion (France, Germany, Spain) the decline in inequality was more muted (O'Rourke and Williamson, 1999: Ch. 6).

Migration and globalization also influenced wage differentials by skill. As migrants were largely unskilled, and increasingly so over time, the largest wage effects were felt among unskilled workers. One study found that net migration had the effect of increasing the skill premium in the United States but narrowing it in France, the UK, Spain, and Italy (Betrán and Pons, 2004). Not surprisingly, this effect is only observed after controlling for a wide range of other forces including trends in technical and structural change as well as key shifts in labor market institutions. Nevertheless, the effects of migration on incomes and their distribution were among the forces that led ultimately to rising barriers to migration.

Immigration Policy

As migration to the New World ascended to ever greater heights in the two decades before World War I, the pressures for restricting immigration mounted. And especially so in the United States, which imposed a literacy test in 1917 to be followed by the first immigration quota in 1921. It has been suggested that the rise in immigration sowed the seeds of its own destruction in the form of a policy backlash. This policy response can be better understood by asking two questions. First, who gains and who loses from migration? And second, who is in a position to do something about it (Foreman-Peck, 1992)?

The answer to the first question is that those most affected were typically low skilled blue-collar workers in the New World. The answer to the second question depends on who has the vote. As the franchise widened, it typically percolated down the hierarchy of class and income, diluting the political weight of landowners and capitalists. At the turn of the twentieth century, voting rates were about one-third for adults in the United States but less than 10% in Latin America where the *Latifundia* retained its grip on power (Engerman and Sokoloff, 2005). Consequently, immigration restrictions came earlier in the United States than in Latin America. In the British Dominions, which were relatively democratic, immigration policy was tightened, but not decisively until the early 1930s.

In the United States, the movement toward restriction began in the 1880s with a number of piecemeal restrictions such as the Chinese Exclusion Act (1882) the 'Gentlemen's agreement' with Japan (1907), tighter inspection, restrictions on contract labor and a head tax. In other settler countries there was a similar trend toward restrictions and exclusion, such as the White Australia Policy. The trend is also evident in the decline in the subsidized passages offered to immigrants, as in Australia after 1913 and Brazil between 1917 and 1927. There is some evidence that the hardening of immigration policies

was underpinned by slow real-wage growth and increasing inequality, as well as by the scale of immigration itself (Timmer and Williamson, 1998). But the timing of major restrictions was associated with big shocks: war and depression. In the United States, pressure for restrictions mounted over two decades before political interest groups finally coalesced to pass the 1917 Immigration Act (Goldin, 1994).

One interesting question is what underlay the public attitudes toward immigration. One possibility is that southern and European immigrants were seen increasingly as undermining the existing Anglo-Saxon culture, while those from Asia were an even greater threat. Another is simply the perceived effect of labor market competition in unskilled labor market. One test of this hypothesis suggests that the latter was uppermost in the United States during the 1890s. It was the scale of immigration rather than the source country composition that was the more important (Richardson, 2005). Labor market conditions were also important; the Emergency Quota was introduced in the United States just as the unemployment rate increased from 5.2% in 1920 to 11.7% in 1921.

The End of the Age of Mass Migration

The US Immigration Acts of 1921 and 1924, which introduced immigration quotas, are often seen as putting an abrupt end to the age of mass migration. Quotas based on country of origin fell particularly heavily on the countries of southern and eastern Europe. In Australia, Canada, and South Africa severe restrictions were introduced in the early 1930s. As **Figure 1** shows, in the 1920s emigration from Europe fell well below the peak decade before 1914, and in the 1930s it fell even further. However, it is likely that immigration from some European countries (those on the downswing of the emigration cycle) would have diminished anyway. The world depression of the 1930s, which was particularly severe in the New World, discouraged immigrants from most European countries except those fleeing totalitarian regimes.

The deglobalization of the world economy during the interwar period reversed some of the pre-War trends. The composition of emigrants shifted back toward northwest Europe, and their occupational skills increased, but there was also a shift toward family reunification (Hatton and Williamson, 2005: p. 186). The trend in the wage premium for skill was also reversed. This trend was more marked in the New World than the Old, and, it was also supported by the expansion of education.

In the post-World War II period, emigration revived and grew as prosperity returned to the world economy. But it did not match the heights of the decade before the World War I. One reason is that migration chains, which had been such an important factor in the earlier period, had been broken by 30 years of war and economic upheaval. Another was that under more buoyant economic conditions, prewar policies became more binding and were subsequently loosened, notably in Australia and Canada. Emigration from Europe grew over the following decades but not as fast as it had in the 50 years before 1914. This was partly due to continuing the rapid growth of living standards in Europe and their convergence on those of destination countries such as the United States.

From the 1960s United States, Canada, and Australia adopted immigration policies that discriminated less by source country and (in the latter two cases) more according to skill and qualifications. As a result, Europeans declined as a proportion of immigrants into the United States – from more than half in the 1950s to 10% in the 1980s (Hatton and Williamson, 2005: p. 208). This period also marked the transition of Europe from a region of emigration to one of immigration. At the same time countries in Asia, Africa, and the Caribbean entered a phase comparable with that of Europe in the age of mass migration.

Migration to and from Latin America

Douglas S Massey, Office of Population Research, Princeton University, Princeton, NJ, USA

Abstract

Over the course of history, Latin America has been very strongly shaped by migration. The aboriginal peoples arrived around 11 000 years ago, and by 1492 had expanded to around 54 million people. The modern history of the region begins in 1492 with the arrival of the Spanish followed closely by the Portuguese, whose germs decimated the indigenous population and transformed Latin America into a region of European immigration. The inflow of European immigrants was modest during the colonial era, especially in comparison to the importation of African slaves, but immigration expanded after independence during the nineteenth and early twentieth centuries, and Argentina and Brazil eventually became immigrant receiving societies on a par with Canada and the United States. In the postwar period, only Argentina persisted as an immigrant receiving society, but its inflow now came from neighborhood countries in South America rather than Europe. Migration to the United States began in Mexico in the early twentieth century and spread to Puerto Rico in the 1940s and then to Cuba and the Dominican Republic in the 1960s. Migration to the United States from Central and South America dates mainly from the 1980s, but at the same time many migrants also began moving to Europe, especially from South America. Much of the migration to Europe has dried up since the Great Recession, but migration to the United States continues. Whereas much of the migration from Mexico was unauthorized during the period from 1965 to 2008, undocumented Mexican migration appears to have ended owing primarily to Mexico's demographic transition.

Early Migration Patterns

As with all nations in the western hemisphere, the countries of Latin America have been strongly shaped by international migration. The first immigrants, of course, were the aboriginal peoples who crossed the Bering Straits some 11 200 years ago (Dillehay, 2000). The next major immigration dates from 1492, when Christopher Columbus arrived on American soil. At that time the aboriginal population of the Americas is estimated to have been around 54 million, though some scholars put the figure much higher. By 1650, however, the aboriginal population had fallen to around 6 million owing mainly to the lack of resistance to infectious diseases brought by Europeans, but also by the disintegration of their civilizations in the wake of European colonization (Denevan, 1992).

In the centuries after 1492, the population of Latin America grew mainly from the arrival of the European colonists and births to them and their descendants. In addition to the Spanish, colonizers from Portugal, Britain, France, and the Netherlands vied for dominance in the Americas. Islands in the Caribbean ended up being colonized by all these nations, whereas the better part of North America fell under British control while Mexico, Central America, and most of South America became colonies of Spain, with the major exception of Brazil, which Pope Alexander gave to the Portuguese under the Treaty of Tordesillas in 1493 (Lockhart and Schwartz, 1983). Ever since then the Portuguese- and Spanish-speaking countries have collectively been known as Latin America.

Colonization by Spain and Portugal occurred mainly for the purpose of wealth extraction, and early immigrants from the mother countries were relatively small in number and disproportionately dominated by men, leading to considerable procreation with indigenous women to produce a new mestizo population (Lockhart and Schwartz, 1983). Of far greater consequence than the arrival of Spanish and Portuguese immigrants, however, was the large-scale importation of African slaves. According to Klein (1999), over the three centuries of the slave trade about 1.7 million Africans were brought into Spanish America and 3.9 million entered Brazil.

European immigration into Latin America during the Colonial Period generally remained modest, as the rulers of both Spain and Portugal prohibited the entry of immigrants from other European countries to guarantee control over their dominions (FitzGerald and Cook-Martín, 2014). The Wars of Independence from Spain were a drawn-out 15-year affair that began in 1810, but by 1825 all countries in Latin America had achieved independence and began to embark on various nation-building projects. Over the course of the nineteenth century, Latin American governments adopted policies to encourage immigration from Europe with the goal of modernizing and 'whitening' their populations (FitzGerald and Cook-Martín, 2014).

Although the success of these policies was modest in most nations, Argentina and Brazil did emerge as countries of mass immigration during the nineteenth century and by 1900 the percentage of foreign-born reached around 7% in Brazil and 30% in Argentina, compared to around 15% in the United States (FitzGerald and Cook-Martín, 2014). As in the United States, mass migration from Europe was brought to a halt by the First World War and after a brief revival in the 1920s finally ended for good with the onset of the Great Depression (Massey, 1995).

In the postwar period, with the sole exception of Argentina countries throughout Latin America were transformed from nations of immigration to nations of emigration (Durand and Massey, 2010). Although Argentina continued to take in immigrants, the source nations shifted from Europe to South America, led by Chile and then in decreasing order including Uruguay, Paraguay and Bolivia, and Peru (Massey et al., 1998). There was significant migration into Venezuela during the oil boom of the 1970s, especially from Colombia, but it has not

 http://dx.doi.org/10.1016/B978-0-08-097086-8.31124-2

persisted, and Venezuela is now a country of emigration, particularly but not only to the United States.

Mexico–US Migration

Migration from Latin America in the modern period has, not surprisingly, been directed primarily to the United States. The oldest and largest flow of Latin Americans to the US is from Mexico. The southwestern US states, of course, were once part of Mexico, but only around 50 000 Mexicans remained north of the border after annexation (Jaffe et al., 1980) and once the border was finally agreed upon in 1854, there was little systematic emigration northward (Massey et al., 2002). Indeed, the border did not physically exist except as a line on a map, and movement back and forth was mostly local for decades (the Border Patrol was not founded until 1924).

Large scale migration from Mexico to the USA dates from the early twentieth century. During the late nineteenth century Mexican President Porfirio Díaz brought in American railroads in order to promote industrialization and development (Cardoso, 1980). The railroads sparked an economic boom in the western US by linking the region's mines, forests, and farms to the burgeoning industrial centers of the Northeast and Midwest, creating a huge demand for labor. The new rail lines also connected Mexico's mines and haciendas to the US markets to generate a rapidly growing trade. The first Mexican migrants to the United States were recruited by railroads around the turn of the century to replace the Chinese immigrants who had been barred from entry by the Chinese Exclusion Act of 1882 (Cardoso, 1980).

Migration from Mexico was modest until 1907, however, when the United States negotiated its 'Gentlemen's Agreement' with Japan to bring an end to Japanese immigration, which up to that point had been the principal source of farm labor (Massey et al., 2002). Desperate for labor, growers sent recruiters down the rail lines into Mexico looking for workers, initiating a new and much larger outflow northward. Whereas annual immigration from Mexico averaged just 1100 persons per year between 1900 and 1907, by 1912 the figure had grown to 22 000.

Once the United States entered the First World War in 1917 and military mobilization drained manpower from the civilian economy, labor demand boomed; and when the United States enacted restrictive quotas to block mass European migration in 1920, the demand for Mexican labor surged again to produce what historians have called a 'flood tide' of Mexican immigration to the United States (Cardoso, 1980). During the 1920s, the annual immigration from Mexico rose to 50 000 persons per year with another 15 000 arriving on temporary work visas. From 1907 through 1929, a total of 686 000 legal immigrants and 226 000 temporary workers entered the United States, with many of the latter simply staying on to work when their visas expired (Massey et al., 2002).

What ended the flood tide was the Great Depression, which not only eliminated labor demand, but also ushered in a program of mass deportations (Hoffman, 1974; Balderrama and Rodríguez, 2006). From 1929 to 1939, 469 000 Mexican immigrants were forcibly repatriated and many more returned home on their own, cutting in half the number of Mexicans living in the United States (Massey et al., 2002). Once the United States entered the Second World War, however, war mobilization once again created labor shortages, especially in agriculture, and the United States replaced the welcome mat by creating the Bracero Program, a binational accord that arranged for the annual entry of Mexican workers on temporary visas (Galarza, 1964).

Although originally deemed a temporary wartime measure, at the behest of growers it was expanded during the postwar years to reach a peak in the late 1950s when the number of Bracero entries peaked at 450 000, with another 50 000 entering as legal immigrants (Calavita, 1992; Massey et al., 2002). In the early 1960s, however, Congress began to wind down the program and formally eliminated it in 1965. Over the course of the program's existence, however, 4.7 million Braceros entered the country, along with around 600 000 legal immigrants.

In addition to ending the Bracero Program, in 1965 the US Congress acted to impose the first ever numerical limits on immigration from the western hemisphere, capping the total at 120 000 per year. By 1976, the hemispheric cap had been replaced by a single worldwide cap of 290 000 and all countries were given an annual quota of just 20 000 legal immigrant visas. From the late 1950s to the late 1970s, Mexico thus went from access to 450 000 temporary visas and 50 000 permanent resident visas to just 20 000 resident visas and no work visas. Economic conditions on both sides of the border had not changed, however, and over the course of the Bracero years hundreds of thousands of migrants had established connections with employers north of the border and elaborated well-developed social networks (Massey et al., 1987). As a result, when opportunities for legal entry evaporated, migrants simply continued to migrate without authorization, ushering in the era of undocumented migration (Massey et al., 2002).

From 1965 to 1979 the number of undocumented entries steadily rose but then stabilized as the outflows reached the levels observed in the late 1950s, except that now the migrants were labeled as 'illegal' (Massey and Pren, 2012). Being 'illegal' they were by definition 'lawbreakers' and 'criminals' and framed by politicians and bureaucrats as a grave threat to the nation, bringing about the rise of a 'Latino threat narrative' in the mass media (Chavez, 2001, 2008). In response to the perceived threat, Congress allocated more funds, equipment, and personnel to the Border Patrol, which of course, produced more apprehensions even though the actual inflow had stabilized. More apprehensions were taken as self-evident proof of the accelerating 'invasion,' which brought more resources to the Border Patrol, thereby generating more apprehensions (Massey and Pren, 2012).

During the 1980s and 1990s, therefore, rising apprehensions and enforcement entered a mutually reinforcing cycle of circular that ratcheted border enforcement up to unprecedented levels. Paradoxically, however, the exponential growth of border enforcement had little effect on the number of undocumented migrants entering the United States. Instead it had a profound effect on the number of migrants returning to Mexico. Prior to the mid-1980s, migration from Mexico had been overwhelmingly circular. From 1965 to 1985 around 85% of undocumented entries were offset by departures, and

the net annual increase in the undocumented population was small (Massey and Singer, 1995). Even among legal immigrants, return migration was common. Estimates suggest that during the 1970s, annual out-migration of legal Mexican immigrants averaged about 20% of legal in-migration (Warren and Kraly, 1985). Of those legal immigrants who entered the country in 1970, around 56% were estimated to have returned by 1979 (Jasso and Rosenzweig, 1982).

The militarization of the border, however, dramatically increased the costs and risks of undocumented border crossing; and in response, migrants quite logically stopped crossing the border – not by staying in Mexico but by remaining in the United States once they had achieved entry (Massey et al., 2002). During the 1990s and 2000s, circulation ceased as the probability of return migration plummeted (Rendall et al., 2011). The inevitable results was a boom in the undocumented population which rose from under 2 million in 1988 to peak at about 12 million in 2008 (Wasem, 2011).

Over the same period 5.4 million legal immigrants entered from Mexico, about 2.3 million of whom were former undocumented migrants who had legalized under the provisions of the 1986 Immigration Reform and Control Act, the rest of whom were mostly sponsored by family members who were US citizens. Parents, spouses, and minor sons and daughters of citizens are eligible for entry outside of the annual quota, and as US policies became increasingly hostile toward noncitizens, legal Mexican immigrants naturalized in record numbers.

The key date was 1996, when US legislation declared legal immigrants ineligible for many social benefits, declared them deportable for often minor offenses, and abridged the rights of noncitizens to challenge removal orders (Zolberg, 2006). While the number of Mexican naturalizations averaged just 23 000 per year before 1996, afterward the average rose to 123 000, creating 2.1 million new citizens with the right to bring in relatives outside the quotas. At the same time, the US Congress quietly began expanding temporary worker migration from Mexico. Whereas in 1993 only 23 000 temporary worker entries were recorded, by 2008 the figure had reached 361 000.

In 2008, of course, the Great Recession brought the US economy to a standstill, and unemployment soared. Between 2008 and 2009, the number of undocumented residents fell by a million and since then has fluctuated around 11 million. Although temporary worker migration and legal immigration from Mexico also dipped, they have since revived but undocumented migration from Mexico appears to have stopped, with few people entering and few of those already present in the United States leaving (Passel et al., 2012).

The apparent end of undocumented migration is partially explained by the weakness of US labor demand and the expansion of opportunities for legal entry, but the principal reason is the dramatic decrease in the rate of labor force growth within Mexico (Hanson and McIntosh, 2010). The current fertility rate is roughly at replacement level and Mexico has become an aging society, dramatically reducing the potential supply of Mexican workers. Circularity has resumed within the Mexico–US migration system, but now most of those moving back and forth across the border do so in legal status, either as temporary workers or as legal immigrants.

Non-Mexican Migration from Latin America

Aside from Mexico, the principal sources of migrants from Latin America to the United States prior to 1980 were Puerto Rico, Cuba, and the Dominican Republic. As US citizens, Puerto Ricans are technically not immigrants and can come and go as they please. The boom years of Puerto Rican migration were from 1940 to 1970, when the island was transforming from a rural to an urban-industrial economy and when the demand for workers in New York's service and garment industries was strong. Since 1970, however, net migration has fluctuated around zero and the island-born population is shrinking and the second and third generations are increasingly moving away from New York (Acosta-Belen and Santiago, 2006).

Immigration from Cuba and the Dominican Republic are both products of the Cold War. Cuban emigration to the United States was spurred by Castro's socialist revolution, which drove out the entrepreneurial, professional, and middle classes during the 1960s and 1970s (Portes and Bach, 1985). Beginning with the Mariel boat lift in 1980, however, Cuban migrants have increasingly been drawn from the lower middle and working classes (Portes and Stepick, 1993). Mass migration from the Dominican Republic dates from 1965, when the United States occupied Santo Domingo to quell a left-wing rebellion led by students, and the ambassador there was ordered to make residence visas generously available to Dominican students and other members of the middle class to get them out of the country, seeding a legal inflow that proceeds to this day (Riosmena, 2010). From 1980 to 2010, some 674 000 Cubans and 939 000 Dominicans entered the United States as legal immigrants.

Migration from Central America to the United States dates from the 1980s when the United States intervened militarily in the region in an effort to topple the leftist Sandinista regime in Nicaragua and suppress leftist insurgencies in El Salvador, Guatemala, and Honduras. The resulting wave of civil violence and economic turmoil generated large flows of refugees heading toward the United States. Whereas Nicaraguans, fleeing a left-wing regime, were welcomed and granted an easy path to legal permanent residence, Salvadorans, Guatemalans, and Hondurans had the misfortune to flee countries governed by right-wing regimes allied with the United States and were therefore deemed economic rather than political refugees and most entered without authorization. As of 2010, around two-thirds of all immigrants from these countries living in the USA were undocumented (cf Hoefer et al., 2011; Acosta and de la Cruz, 2011). Between 1980 and 2010, 205 000 legal immigrants entered from Nicaragua, compared with 1.2 million from El Salvador, Guatemala, and Honduras, helping to turn Hispanics into the nation's largest minority group.

Migration from South America also dates from the 1980s and is attributable mainly to the debt crisis and the 'lost decade' of the 1980s when economic growth flattened and structural adjustment policies were imposed by global lenders in Washington, DC (Massey et al., 2006), though in the case of Colombia out-migration also occurred in response to political violence (Silva and Massey, 2015). From 1980 to 2010, legal immigration from South America totaled around 1.7 million,

with the largest contributors being Colombia (518 000), Peru (320 000), Ecuador (251 000), Brazil (201 000), Venezuela (133 000), and Argentina (100 000). The only country with significant undocumented migration to the United States is Ecuador, whose undocumented population stood at 180 000 in 2010 (Hoefer et al., 2011).

During the 1980s and 1990s migrants from Central and South America also began migrating to Europe in significant numbers (Durand and Massey, 2010). Naturally the largest number went to Spain, where around 1.1 million Latin Americans had settled by 2005 (Padilla and Piexoto, 2007), but there were also significant Latin American populations in Italy (205 000), Britain (113 000), Germany (94 000), Portugal (56 000), and France (47 000). Of these migrants, by far the largest share (88%) came from South America, with the leading sources being Ecuador, Colombia, Bolivia, Peru, Argentina, and Brazil. A significant share of migration from Argentina and Brazil, the two largest countries of European immigration during the early twentieth century, were able to reclaim a European nationality, obtain a passport, and then migrate to Europe as EU citizens. Durand and Massey (2010) have labeled this form of movement transgenerational migration, for citizenship is typically reclaimed through an immigrant grandparent from Germany, Italy, Spain, or Portugal, which extend nationality to third generation descendants of persons born in those countries. Since the Great Recession, Latin American migration to Europe, and particularly Spain and Portugal, has slowed down to a standstill and in some cases reversed.

Abstract

Theorists in a variety of disciplines have offered theoretical explanations for human migration. This article reviews the leading models that have been developed to theorize five facts of human migration: the structural forces that promote 'out-migration' from sending regions; the structural forces that attract 'in-migrants' to receiving societies; the motivations, goals, and aspirations of people who respond to these structural forces by becoming migrants; the social and economic structures that arise to connect areas of out- and in-migration; and the actions taken by states to influence the number and characteristics of immigrants. These models include neoclassical economics, the new economics of labor migration, segmented labor-market theory, social capital, cumulative causation, world-systems theory, and securitization theory.

Social scientists have theorized five basic aspects of human migration in their efforts to explain it: the structural forces that promote 'out-migration' from sending regions; the structural forces that attract 'in-migrants' to receiving societies; the motivations, goals, and aspirations of people who respond to these structural forces by becoming migrants; the social and economic structures that arise to connect areas of out- and in-migration; and the actions taken by states to influence the number and characteristics of immigrants. The ensuing sections review the theoretical perspectives that address these issues, and then offer a theoretical synthesis that includes empirically supported propositions from each one.

Neoclassical Economics

The oldest and best-known theoretical model, neoclassical economics, argues that migration is caused by geographic differences in the supply of and demand for labor (Lewis, 1954; Ranis and Fei, 1961). A region with a large endowment of labor relative to capital will have a low equilibrium wage, whereas an area with a limited endowment of labor relative to capital will have a high wage. The resulting gap causes workers from the low-wage or labor-surplus area to move to the high-wage or labor-scarce region. As a result of this movement, the supply of labor decreases and wages rise in the capital-poor area, while the supply of labor increases and wages fall in the capital-rich area, leading, at equilibrium, to a geographic wage differential that exactly reflects the costs of interregional movement, pecuniary and psychic.

Associated with this macroeconomic theory is an accompanying microeconomic model of individual choice (Todaro, 1976). In this scheme, rational actors decide to migrate because a cost-benefit calculation leads them to expect a positive net return, usually monetary, from movement. Migration is conceptualized as a form of investment in human capital (Sjaastad, 1962). People choose to move where they can be most productive, given their skills; but before they can reap the higher wages associated with greater labor productivity, they must invest in the material costs of travel, the costs of self-support while moving and looking for work, the effort involved in learning a new environment and possibly a different culture, the difficulty experienced in adapting to a new labor market, and the psychological costs of cutting old ties and forging new ones.

Potential migrants estimate the costs and benefits of moving to alternative locations and migrate to where the expected discounted net returns are greatest over their projected working lives. Net future returns are estimated by taking earnings observed in the destination area and multiplying them by the probability of obtaining a job there to derive 'expected destination earnings,' which are then subtracted from earnings estimated for the place of origin (observed earnings times the probability of employment). The difference is then summed over future years and discounted by a factor that reflects the greater utility of money earned in the present than in the future. From this integrated difference, the estimated costs are subtracted to yield the expected net returns to migration. In theory, a potential migrant goes to wherever the expected net returns are greatest.

The New Economics of Migration

In recent years, a 'new economics of labor migration' has arisen to challenge the assumptions and conclusions of neoclassical theory (Stark, 1991). A key insight of this approach is that migration decisions are not made by isolated individuals, but within larger units of interrelated people – typically families or households but also entire communities – and that people act collectively not only to maximize expected income, but also maximize status within an embedded hierarchy to overcome barriers to capital and credit, and to minimize risk.

In developed countries, risks to household income are managed through institutional mechanisms. Crop insurance programs and futures markets give farmers a way of protecting themselves from natural disasters and price fluctuations, whereas unemployment insurance and government transfer programs protect workers against recessions and job loss through structural transformation. Private or government-sponsored retirement programs, meanwhile, offer citizens a means of insuring against the risk of poverty in old age.

In the absence of such programs, households are in a better position than individuals to control risks to economic well-being. They can easily diversify sources of income by allocating different family workers to different labor markets. As

long as economic conditions across labor markets are negatively or weakly correlated, households minimize risk by geographically diversifying their labor portfolios. In the event that economic conditions at home deteriorate and productive activities there fail to generate sufficient income, the household can rely on migrant remittances for support.

Markets for credit and capital are incomplete or inaccessible in many settings, and in the absence of an efficient banking system, migration becomes attractive as a strategy for accumulating funds in lieu of borrowing. Families send one or more workers to a higher wage area to accumulate savings or send them back in the form of remittances. Although most migrant savings and remittances go toward consumption, some of the funds are also typically channeled into productive investment.

A key proposition of the new economic model is that income is not a homogeneous good. The source of the income really matters, and households have significant incentives to invest scarce family resources in activities that provide access to new income sources, even if these activities do not increase total income. The new economics also questions the assumption that income has a constant effect on utility – i.e., a $100 real increase in income means the same thing to a person regardless of community conditions and irrespective of his or her position in the local income distribution. Instead, it holds that households send workers abroad not only to improve absolute incomes, but also to increase them relative to others, and, hence, to reduce relative deprivation compared with some reference group (Stark, 1991). A household's sense of relative deprivation depends on the total income earned by households above it in the income distribution. If utility is negatively affected by relative deprivation, and even if a household's income and expected gains from migration remain unchanged, it may acquire an incentive to migrate if there is a change in other households' incomes.

Segmented Labor-Market Theory

Although neoclassical theory and the new economics of labor migration offer divergent explanations for the origins of migration, both ultimately reduce to microlevel decision models. What differs are the units assumed to make the decision (the individual or the household), the entity being maximized or minimized (income vs risk), the assumptions about the economic context of decision-making (complete and well-functioning markets vs missing or imperfect markets), and the extent to which the migration decision is contextual (whether income is evaluated in absolute terms or relative to some reference group).

Standing distinctly apart from these models is segmented labor-market theory, which argues that migration stems from the intrinsic character of modern industrial societies. According to Piore (1979), migration is not caused by push factors in sending regions (low wages or high unemployment), but by pull factors in receiving areas (a chronic and unavoidable need for migrant workers). The built-in demand for inexpensive and flexible workers stems from three basic features of advanced industrial economies.

The first is structural inflation. Wages not only reflect conditions of supply and demand, but also confer status and prestige that social qualities inhere in jobs. In general, people believe that wages should reflect social status, and they have clear notions about the correlation between occupational status and pay. As a result, employers are not entirely free to respond to changes in the supply of workers. A variety of informal social expectations and formal institutional mechanisms (union contracts, civil service rules, bureaucratic regulations, company job classifications) ensure that wages correspond to the hierarchies of prestige and status that people perceive and expect.

The demand for cheap, flexible labor is also augmented by social constraints on motivation within occupational hierarchies. Most people work not only to generate income, but also to accumulate social status. Acute motivational problems arise at the bottom of any job hierarchy because there is no status to be maintained and there are few avenues for upward mobility. The problem is structural, because the bottom cannot be eliminated from the labor market. Mechanization to eliminate the lowest and least desirable class of jobs will simply create a new bottom tier composed of jobs that used to be just above the bottom rung. Since there must always be a bottom of any hierarchy, motivational problems are inescapable.

Thus, employers need workers who view bottom-level jobs simply as a means to the end of earning money, and for whom employment is reduced solely to income, with no implications for status or prestige. For a variety of reasons, migrants satisfy this need. They begin as target earners, seeking to earn money for a specific goal that will improve their status or well-being at home – building a house, paying for school, buying land, acquiring consumer goods. Moreover, the disjuncture in living standards between origin and destination communities often means that low urban or foreign wages appear to be generous by the standards of the sending society.

The demand for migrant labor also stems from economic dualism. Capital is a fixed factor of production that can be idled by lower demand but not laid off; owners of capital must bear the costs of its unemployment. Labor is a variable factor of production that can be released when demand falls, so that workers bear the costs of their own unemployment. Whenever possible, therefore, capitalists seek out the stable, permanent portion of demand and reserve it for the employment of equipment, whereas the variable portion of demand is met by adding labor. Thus, capital-intensive methods are used to meet basic demand, and labor-intensive methods are reserved for the seasonal, fluctuating component. This dualism creates distinctions among workers, leading to a bifurcation of the labor force.

Workers in the capital-intensive primary sector get stable, skilled jobs working with the best equipment and tools. Employers are forced to invest in these workers by providing specialized training and education. Their jobs are complicated and require considerable knowledge and experience to perform well, leading to the accumulation of firm-specific human capital. Primary-sector workers thus tend to be unionized or professionalized, with contracts that require employers to bear a substantial share of the costs of their idling (severance pay and unemployment benefits). Because of these costs and continuing obligations, workers in the primary sector become expensive to let go; they become more like capital.

In the labor-intensive secondary sector, however, workers hold unstable, unskilled jobs; they may be laid off at any time

with little or no cost to the employer. Indeed, the employer will generally lose money by retaining workers during slack periods. During down cycles, the first thing secondary-sector employers do is to cut payroll. As a result, employers force workers in this sector to bear the costs of their unemployment. They remain a variable factor of production and are, hence, expendable.

The inherent dualism between labor and capital extends to the labor force in the form of a segmented market structure. Low wages, unstable conditions, and the lack of reasonable prospects for mobility in the secondary sector make it difficult to attract local workers, who are instead drawn into the primary, capital-intensive sector, where wages are higher, jobs are more secure, and there is a possibility of occupational improvement. To fill the shortfall in demand within the secondary sector, employers turn to migrants.

In their analysis of the process by which Cuban immigrants were incorporated into the United States, Portes and Bach (1985) uncovered evidence of a third possible sector that blends features of primary and secondary labor markets. Like the secondary sector, ethnic enclaves contain low-status jobs characterized by low pay, chronic instability, and unpleasant working conditions – jobs that are routinely shunned by natives. Unlike the secondary sector, however, they provide immigrants with significant economic returns to education and experience, as well as the very real prospect of upward socioeconomic mobility, thus replicating features of the primary sector.

The existence of a large, concentrated ethnic population creates a demand for specialized cultural products and services that immigrant entrepreneurs are uniquely qualified to fill. In addition, privileged access to the growing pool of migrant labor gives them an advantage when competing with mainstream firms. Migrants working in the enclave trade low wages and the acceptance of strict discipline upon arrival for a greater chance of advancement and independence later on. In order to function effectively over time, therefore, an ethnic enclave requires a steady stream of new arrivals willing to trade low initial wages for the possibility of later mobility, yielding an independent segmented source of labor demand for migrant workers, complementing that emanating from the secondary sector.

World-Systems Theory

Growing out of the historical–structural tradition in social science, world-system theory argues that migration stems from the penetration of capitalist economic relations into noncapitalist or precapitalist areas to create a mobile population (Sassen, 1988). Driven by a desire for higher profits and greater wealth, owners and managers of capitalist firms in core regions enter poor peripheral areas in search of land, raw materials, labor, and consumer markets. Migration emerges in response to the disruptions and dislocations that inevitably occur in the process of capitalist development.

In order to achieve the greatest profit from existing agrarian resources, and to compete within global commodity markets, capitalist farmers seek to consolidate landholding, mechanize production, introduce cash crops, and apply industrially produced inputs such as fertilizer, insecticides, and high-yield seeds. Land consolidation destroys traditional systems of land tenure based on inheritance and common ownership. Mechanization decreases the need for manual labor and makes many agrarian workers redundant. The substitution of cash crops for staples undermines traditional, social, and economic relations based on subsistence; and the use of modern inputs produces high crop yields at low unit prices. All of these forces drive peasants off the land to create a mobile labor force of people displaced from the land.

The extraction of raw materials for sale on global markets requires industrial methods that rely on paid labor. The offer of wages to former peasants undermines traditional forms of social and economic organization based on norms of reciprocity and fixed role relations, and creates incipient labor markets based on new conceptions of individualism, private gain, and social change. At the same time, capitalist firms enter developing regions to establish assembly plants, often within special export-processing zones created by sympathetic governments. The demand for factory workers strengthens local labor markets and weakens traditional productive relations. The insertion of foreign-owned factories into peripheral regions undermines regional economies by producing goods that compete with those made locally; feminizing the workforce without providing factory-based employment opportunities for men; and socializing women for industrial work and modern consumption without providing a lifetime income capable of meeting these needs. The result once again is the creation of a population that is socially and economically uprooted and prone to migration.

The same capitalist economic processes that create migrants in peripheral regions simultaneously attract them into certain highly developed urban areas. The investment that drives economic globalization is managed from a small number of global cities, whose structural characteristics create a strong demand for migrant labor. In order to ship goods, deliver machinery, extract and export raw materials, coordinate business operations, and manage expatriate assembly plants, capitalists in global cities build and expand transportation and communication links to the peripheral regions where they have invested. These links not only facilitate the movement of goods, products information, and capital, but also promote the movement of people by reducing the costs of movement along certain pathways.

The creation and perpetuation of a global trading regime also requires an underlying system of international security. Core capitalist nations have both an economic interest in, and the military means of preserving, geopolitical order, and leading powers thus maintain relatively large armed forces to deploy as needed to preserve the integrity of the global capitalist system. Threats to the stability of that system are met by military force projected from one or more of the core nations. Each military base and armed intervention, however, creates a range of social and political connections that promote the subsequent movement of migrants.

Finally, processes of economic globalization also create ideological or cultural links between core capitalist regions and their peripheries. In many cases, these cultural links are long-standing, reflecting a colonial past in which core countries established administrative and educational systems that mirrored their own in order to govern and exploit a peripheral region. Ideological connections are presently reinforced by mass communications and advertising campaigns directed

from the core urban centers. The diffusion of core cultural patterns and the spread of modern consumption interact with the emergence of a transportation–communication infrastructure to channel migrants disproportionately to global cities.

Social-Capital Theory

Although it was Loury (1977) who first introduced the concept of social capital, it was Bourdieu (1986) who pointed out its broader relevance to human society. According to Bourdieu and Wacquant (1992: p. 119), "social capital is the sum of the resources, actual or virtual, that accrue to an individual or a group by virtue of possessing a durable network of more or less institutionalized relationships of mutual acquaintance and recognition." The key characteristic of social capital is its convertibility – it may be translated into other forms of capital, notably financial capital. People gain access to social capital through membership in networks and social institutions, and then convert it into other forms of capital to improve or maintain their position in society (Coleman, 1988).

Massey et al. (1987: p. 170) were the first to identify migrant networks as a form of social capital. In keeping with Coleman's (1990: p. 304) dictum that "social capital … is created when the relations among persons change in ways that facilitate action," they identified migration itself as the catalyst for change in the nature of social relations. Everyday, ties of friendship and kinship provide few advantages, in and of themselves, to people seeking to migrate. Once someone in a personal network has migrated, however, the ties are transformed into a resource that can be used to gain access to employment and high wages at points of destination. Each act of migration creates social capital among people to whom the new migrant is related, thereby raising the odds of their migration.

Goss and Lindquist (1995) point to migrant institutions as a structural complement to migrant networks, arguing that interpersonal ties are not the only means by which social capital is created and that "migration is best examined not as a result of individual motivations and structural determinations, although these must play a part in any explanation, but as the articulation of agents with particular interests and playing specific roles within an institutional environment…" (p. 345). For-profit organizations and private entrepreneurs provide services to migrants in exchange for fees set on the underground market: surreptitious smuggling across borders; clandestine transport to internal destinations; labor contracting between employers and migrants; counterfeit documents and visas; arranged marriages between migrants and legal residents or citizens of the destination country; and lodging, credit, and other assistance in countries of destination. Over time, individuals, firms, and organizations become institutionally stable and offer another source of social capital to would-be migrants.

Cumulative Causation

The theory of cumulative causation basically argues that human migration changes individual motivations and social structures in ways that make additional movement progressively, likely, a process first identified by Myrdal (1957) and reintroduced to the field by Massey (1990). Causation is cumulative in the sense that each act of migration alters the context within which subsequent migration decisions are made to make additional trips of longer duration more likely. Social scientists have discussed eight ways that migration has cumulatively caused: the expansion of networks, the distribution of income, the distribution of land, the organization of agriculture, culture, the regional distribution of human capital, the social meaning of work, and the structure of production. Feedbacks through other variables are also possible, but have not been systematically treated.

The State Filter

Prior to 1914, the flow of immigrants around the world was relatively free and unconstrained. Although receiving nations imposed qualitative controls that restricted entry on the basis of health, morality, race, and ethnicity, international migration was not numerically restricted and passports did not exist (Zolberg, 2006). Numerical restrictions on immigration and passport controls began to be imposed during the 1920s, and since 1945, national states have sought to regulate both the numbers and characteristics of those who enter their nations for work and residence.

State policies thus actively shape the size and composition of immigrant flows into around the world. By the end of the twentieth century, a consensus had emerged that policies tend to become more restrictive during periods of economic dislocation and distress, during periods when the volume of immigration is or has been high, as well as during periods of ideological insecurity and political conformity (Goldin, 1994; Timmer and Williamson, 1998; Meyers, 2004). Since the events of 11 September 2001, however, immigration has been increasingly 'securitized' by politicians and pundits who frame it as an existential threat conflated with global terrorism, yielding draconian enforcement measures (Bourbeau, 2011; d'Appollonia, 2012).

The securitization of immigration began earliest in the United States, when Ronald Reagan incorporated border control into the rhetoric of the Cold War and framed the Mexico–US border as a bulwark against communists from Central America (Massey et al., 2002); but securitization expanded dramatically during the 1990s in response to a series of terrorist attacks, culminating in 9/11 and the passage of the USA PATRIOT Act (Massey and Pren, 2012). The degree to which restrictive immigration policies actually work depends on a state's capacity to implement and enforce them, of course (Massey, 1999), and given the diffuse, open, decentralized system of the United States, the progressive militarization of its southern border after 1986 backfired by curtailing circular migration, which had long been a characteristic feature of the North American migratory system. In response to rising costs and risks of unauthorized border crossing, Mexicans stopped circulating not by staying in Mexico but by remaining in the United States once the costs and risks along the border had been experienced, thereby increasing the net rate of undocumented migration and accelerating undocumented population growth.

A Theoretical Synthesis

Contemporary migration appears to originate in the social, economic, political, and cultural transformations that accompany the penetration of capitalist markets into nonmarket or premarket societies (world-systems theory). In the context of a globalizing economy, the entry of markets into peripheral regions disrupts existing social and economic arrangements and brings about the displacement of people from customary livelihoods, creating a mobile population of workers who actively search for new ways of earning income, managing risk, and acquiring capital. Most of these people seek to assure their well-being is by selling their labor on emerging markets (neoclassical economics).

Because wages are generally higher in urban than in rural areas, much of this process of labor commodification is expressed in the form of rural–urban migration; but wages are even higher, in developed countries overseas, and the larger size of these transnational wage differentials inevitably prompts some adventurous people to sell their labor on international markets by moving abroad for work. International wage differentials are not the only factor motivating people to migrate, however. Evidence also suggests that people displaced in the course of economic transformation move not simply in order to reap higher lifetime earnings by relocating permanently to a foreign setting. Rather, households struggling to cope with the jarring transformations of early economic development also use temporary labor migration as a means of managing risk and overcoming barriers to capital and credit (the new economics of labor migration).

While the early phases of economic development promote emigration, transformations in advanced postindustrial economies yield a bifurcation of labor markets. Jobs in the primary labor market provide steady work and high pay for native workers, but jobs in the secondary sector offer low pay, little stability, and few opportunities to generate a structural demand for migrant workers (segmented labor-market theory). This process of labor market bifurcation is most acute in global cities, where a concentration of managerial, administrative, and technical expertise leads to a concentration of wealth and a strong ancillary demand for low-wage services (world-systems theory). Unable to attract native workers, employers turn to immigrants and initiate immigrant flows directly through formal recruitment (segmented labor-market theory).

Although often instrumental in initiating migration flows, recruitment becomes less important over time because the same processes of economic globalization that create mobile populations in developing regions, and which generate a demand for their services in certain cities, also create links of transportation, communication, politics, and culture to make the movement of people increasingly cheap and easy (world-systems theory). However when a migration stream begins, it displays a strong tendency to continue because of the growth and elaboration of networks (social-capital theory). The concentration of migrants in certain destination areas creates a 'family and friends' effect that channels later cohorts to the same places and facilitates their arrival and incorporation. If enough migrants arrive under the right conditions, an enclave economy may form, which further augments the specialized demand for migrant workers (segmented labor-market theory).

The spread of migratory behavior within sending communities sets off ancillary structural changes, shifting distributions of income and land, and modifying local cultures in ways that promote additional out-migration. Over time, the process of network expansion may become self-perpetuating because each act of migration causes social and economic changes that promote additional movement (the theory of cumulative causation). As receiving areas implement restrictive policies to counter the rising tides of migrants, they create a lucrative niche into which enterprising agents, contractors, and other middlemen move to create migrant-supporting institutions, providing migrants with yet another infrastructure capable of supporting and sustaining movement (social-capital theory). In cases where state capacity to impose immigration controls is limited, social capital formation and cumulative causation can promote migration despite restrictions, which may backfire by deterring out-migration rather than in-migration.

During the initial phases of out-migration, the effects of capital penetration, market failure, social network expansion, and cumulative causation dominate to cause a rapid upsurge of the flow; but, as the level of emigration reaches high levels, and the costs and risks of movement drop, movement is increasingly determined by wage differentials (neoclassical economics) and labor demand (segmented labor-market theory). As economic growth in sending areas occurs, wage gaps gradually diminish and well-functioning markets for capital, credit, insurance, and futures come into existence, progressively lowering the incentives for emigration. If these trends continue, the country or region ultimately becomes integrated into the global or national economy, whereupon it undergoes a transformation: massive out-migration progressively trails off and shifts to a pattern of circulatory movement whose net balance fluctuates in response to changing economic conditions at origin and destination (Hatton and Williamson, 1998), yielding a characteristic curve in the course of the mobility transition that Martin and Taylor (1996) have called the "migration hump."

Migrations, Colonizations, and Diasporas in Archaeology

Abstract

Demographic density, as much as the ideas of conquest and discovery, has always led to population movements since the origins of humanity. These are evidenced by stylistic and symbolic processes, as much as in art and technology, as in ways of life. Their systematic reconstruction enables the creation of 'historical' maps from the distant past to modern peoples today.

Humanity possesses an efficient adaptive ability due to the technological and cultural changes that it has accomplished. These changes have permitted hominid groups to occupy varied habitats that would have been incompatible with their natural anatomical capacities alone. From the beginning, one of the essential criteria defining humanity was mobility. The appeal of displacement was apparently based on the requirements of thought: courage, imagination, and challenge. Through time, various kinds of migrations were undertaken; in each case, it was a matter of overcoming new, successively encountered, constraints: steppe, tundra, and oceans. We distinguish seasonal migrations (hunting) from definitive displacement (colonization). We also recognize the cases of diaspora (where existing groups remained separate from the new ones) and of acculturation (groups living in symbiosis with each other).

Migrations are the basis for widespread human presence in the world today. The specificity of human migrations is related to their adaptive mode, and is entirely different from animal dispersions. The flexibility of cultural systems permits, in principle, their adaptation to any natural environment encountered. Thus, this form of expansion can be broader and more intense than modifications of a biological order. Demographic developments occurring in human populations due to technological adaptations are often evoked to justify such human migrations. However, causes of a metaphysical order seem to act more powerfully to drive populations toward dispersal.

Regardless of the cause(s), migrations are a constant, observable in human behavior up to the present. In reality, a sedentary way of life seems to constitute an exception rather than the rule, considering the immense history during which humanity was exclusively nomadic. Once technoeconomical capacities were adequate, they were immediately put to use for displacements, which required new forms of adaptation of the social group, including the readjustment of values.

In terms of methodology, we often distinguish seasonal migration from permanent displacement. In practice, the distinction is reduced to a notion of scale, applied to time, rates, and proportions of migrations. Human territorial extension was a result of perpetual movement, and only large-scale phenomena can be considered permanent where diversity is constant and processes unending.

From the beginning, a distinctive feature of humans was their ability to leave the natural environment favorable to the way of life followed by other primates (Klein, 1989). Via bipedalism and the manipulation of objects, humans were able to leave the protective and nourishing environment of the tropical forests. The bipedal position, adapted to open environments, provoked these displacements, while a meat-based diet compensated for the loss of calories from vegetal foods, which were greatly reduced in the new savannah environments. Migration and the cultural adaptation that bipedalism and such a diet necessitated were therefore the driving forces behind the origins of humanity. The freedom acquired in relation to environmental determinism became the inevitable destiny of humanity, under the ultimate threat of its complete disappearance (Böhme, 1996).

The natural environments successively encountered in the process of hominid expansion toward northern latitudes required the development and adaptation of more complex and suitable physical forms (Wolpoff, 1998; Klein, 1989). These migratory movements, as early as 2 million years ago, extended north and east of the Old World, each time reaching new areas and demanding new dietary resources. The two keys explaining the range and the success of these migrations are the production of tools and the use of fire. Both were invented through imagination and audacity, forces that alone hold the explanation for such pioneering enterprises (**Figure 1**). Humanity eventually progressed throughout history according to this continuous thread of making evermore extended territorial conquests – toward the islands, the Americas, the moon. No force other than imagination pushed humanity, yet – retrospectively – we can retrace the high points, the pauses, the adaptations, and changes in rhythm. Within the confines of already-occupied areas, complex phenomena resulting from contacts and exchanges proper to humanity were produced. These phenomena can be classified in categories such as acculturation, colonization, and diaspora.

To appreciate the movements of migration toward unoccupied areas, the examination of conquests on the margins can

Figure 1 The first Acheulean migration in Europe passed from Africa to Spain via Gibraltar, after an earlier population from Asia arrived in Europe with a flake-based industry. After Roe, D.A., 1981. The Lower and Middle Palaeolithic in Britain. Routledge, London.

be instructive. For diffusion to the high seas of Oceania, migration is clearly linked to the mastery of navigation. An analogous situation is found on the northern margins of Europe during the Late-glacial: Hamburgian and Magdalenian reindeer hunters overcame climatic constraints as temperatures rose (Figures 2–4).

In order that massive displacements toward unoccupied regions may take place, technological equipment, in the subtlety of their elaboration, permitted adaptation to new environments and not simply to climatic modifications. This 'call to conquest' and the temptation of mobility seem to act as the only agents leading to displacement. Within occupied areas, more limited migratory cycles can be observed, for example, seasonal rounds (following the displacement of herds), or for ceremonial reasons (trade/exchange, marriage). These are such that potential mobility remains constant and is effectively begun from the moment that a threshold of ability is attained in relation to new constraints in a foreign environment. Technology, hunting, and group solidarity therefore had to become specialized before a migration could take place outside the original area of development (Otte, 1995).

The conquest continues east to Easter Island and north to Scandinavia. The case of the Americas remains perhaps the most revealing; migrations first followed the Siberian coast, then the islands of Beringia, and finally the northwest Pacific Coast. Migratory waves then switched from the high latitudes to the southern opening formed by the Californian coast. The invasions, extremely intense in North America, passed through a bottleneck between glaciers where modes of adaptation could reverse abruptly. In other terms, it seems quite probable that the first migration took place via coasts, directly toward the south. This would explain the early site dates in South America (e.g., Brazil). Moreover, the northern plains were colonized later, either after the separation of the glaciers to the north or even by a return, coming from the south after having crossed the continent only in Central America. As means of communications were developed, displacements were organized, first by coastal or marine environments, later by land. The modes of occupation of the prehistoric Americas still reflect migratory waves following the first conquest (Dixon, 1999).

The contacts with the cultural milieus already in place during migrations appear more complicated than simple adaptation to new environments. Some classic cases are known. One example is the arrival of modern humans in Europe, evidence of which is given both by a new anatomical form and by a completely novel system of symbolic and technological behaviors. We can be certain at

Figure 2 (a) Magdalenian movement in hilly regions during the Dryas I. (b) Dual movement during the Late-glacial, toward the northern plains and west across the then-dry North Sea. After Otte, M., 1996. Aires culturelles au Paléolithique supérieur d'Europe. In: Mohen, J.P. (Ed.), La vie préhistorique. Faton, Dijon, France, pp. 286–289.

least that a migratory wave from external populations can be revealed at the level of their customs, and attested by archaeology. A point of contact is then established, as it was with the Celts or the Germans, whose migrations were – elsewhere – attested by texts. A double control confirms the validity of archaeological data in the study of migration: anthropological on one hand, historical on the other. The Aurignacian trail crossed a Europe already regularly occupied by Neanderthals of the Mousterian culture.

The two milieus are clearly opposed, according to archaeological data, but on the margins, acculturation phenomena were produced locally, evidenced by 'mixed' assemblages: the Chatelperronian industry, foliate point cultures (Figure 5). In this way, tertiary phenomena (acculturation) emerge, from which later cultures develop. The case

Figure 3 Two forms of migrations are observed in the northern plains during the Late-glacial: conquest in the eastern hilly regions and seasonal movements from north to south, following fluvial axes. After Otte, M., 1997b. Paléolithique final du nord-ouest, migrations et saisons. In: Fagnart, J.P., Thévenin, A. (Eds.), Le Tardiglaciaire du Nord-Ouest de l'Europe. CTHS, Paris, pp. 353–366.

Figure 4 While Magdalenian migrations followed the axis of the plateaus, the northern plains were crossed by Hambourgian and Creswellian groups. After Otte, M., 1997b. Paléolithique final du nord-ouest, migrations et saisons. In: Fagnart, J.P., Thévenin, A. (Eds.), Le Tardiglaciaire du Nord-Ouest de l'Europe. CTHS, Paris, pp. 353–366.

Figure 5 The first migration by modern humans in Europe met the established local Neanderthals. The Aurignacian remained homogeneous with respect to people and traditions. At the margins of this movement, contact phenomena arose: the acculturation of the Neanderthals by the Aurignacian culture. After Otte, M., 1995. Traditions bifaces. Les industries à pointes foliacées d'Europe centrale. Paléo (Suppl. 1), 195–200.

of the Aurignacian, at first clearly imposing itself, then completely disappearing in favor of a local Gravettian, forms a good example of migrations melting into a new and finally dominant population. These types of migrations to already occupied regions occur throughout the Palaeolithic with more or less clarity (Otte, 1997b).

Another instructive case is illustrated by the southern Solutrean industry, which includes one element that seems to originate in North Africa and another from northern Gravettian migrations (Otte, 1997a). When these two movements from north and south met, a new region of acculturation made its appearance, provoking the creation of a culture (the Solutrean) lasting several thousand years in Southwest Europe. Only general artistic trends reflect continuity with the preceding period, tracing their development under a harmonious form. Other elements of a stylistic character are profoundly modified at the end of the period of contact between these two opposing migratory waves.

A third migratory model also appears within the archaeological domain: the establishment of colonies, far from their points of origin but maintaining contact via exchanges with the intervening regions. This mode of colonization is well known from recent historical periods: Greek and Roman colonies, and later European colonial expansion. Colonial migrations first appear during the Linearbandkeramik (LBK) period of the Neolithic, 6000 years ago, when early Neolithic groups expanded across the European continent from the east and southeast (Otte, 2001).

The settlers traveled in a distinctive manner, under a permanent form but without modifying their own way of life, in this way maintaining contact with their original culture. The LBK people had architecture and an urbanism in balance with a stable economy (agriculture and animal husbandry), and an effective and appropriate technology (production of ceramics, grindstones, and polished adzes). A coherent way of life was harmonized with a new, totally mastered, environment. Contacts with indigenous populations modified the internal equilibrium acquired by the new arrivals. Archaeological data clearly illustrate this migratory model, with a great constancy presented by habitats and ceramic styles (Figures 6 and 7). Contacts are revealed by the long-distance exchange of raw materials from previously occupied regions. The impression of a strong cultural unit thus dominates the entire area of expansion of the archaeological culture.

Finally, the diaspora shows people whose migrations have integrated them into other milieus without affecting the structural articulation created by their own traditions. Modern cases are eloquent and well known, such as the Armenians, the Roma (gypsies), and the Jewish groups. Archaeological cases of widely dispersed cultures superimposed onto local traditions yet remaining stable, are also known. For example, the Bell Beaker people during the Neolithic period, identified by the presence of distinctive, globular goblets, were spread across Western Europe, particularly along seacoasts and rivers. Their simple burials, individual and with highly standardized grave goods, suggest the existence of a network of traveling merchants, perhaps linked to the exchange of the first metals

Figure 6 The LBK appears as a movement of colonization from a cultural center in modern Hungary. The settlers kept contact with nuclear areas and remained stable. After Otte, M., Noiret, P., 2001. Le Mésolithique du Bassin Pannonien et la formation du Rubané, L'Anthropologie 105 (3), 409–419.

Figure 7 The LBK expansion represents the clearest model of prehistoric colonization: artifacts remained unchanged over a vast territory and are radically different from those found in preceding periods in the regions crossed. After Keeley, L.H., 1996. War before Civilization. Oxford University Press, Oxford.

(Figure 8). Cultural links remain obvious between these different populations, because they participated in an extended exchange network over a vast territory. However, not a single center seems to exist as a unifying and referential model for the culture.

Migrations in archaeological contexts are thus frequent and refer to all humanity. We are able to recognize clear traces throughout virgin territories such as the Americas or northern Europe; here it is the artifacts themselves that directly retrace the paths of human expansion. Stylistic criteria permit us to recognize different cultures and to follow their movement across space and through time.

Mitigating cases where such migrations are superimposed on indigenous populations demand different and more elaborate methods appropriate to the human sciences. The styles of equipment must be compared between the two groups in order not only to distinguish them but also to identify possible symbioses or influences. Maps of dispersion aid, stage by stage, in understanding archaeological evidence across space (Figure 9). To distinguish the influences of possible convergences, and similarities produced in different environments but at similar developmental stages, critical analysis must be applied to the archaeological record. The classic case, for example, is the Late Mousterian in Europe, where the same 'inventions' are known across all cultural environments in different regions but in similar circumstances. Migration can only appear in the global distribution and cohesion of a phenomenon, paired with territorial expansion. The more stylistic criteria are elaborated, the less random they are, and the more therefore they correspond to the system of values conveyed by a homogeneous population. It is this general key that archaeologists follow in their reconstructions of displacement. Although this law is not infallible and demands constant vigilance, comparisons with recent culturally well-defined peoples, permit us to ensure its effectiveness (Figure 10).

Figure 8 Small groups of Bell Beaker people had an enormous territorial expansion. They are characterized by graves, a particular ceramic form and copper objects. Their distribution, superposed on to local traditions, evokes the diaspora observed in historical times. After Briard, in Mohen, J.P. (Ed.), 1996. La vie préhistorique. Faton, Dijon, France.

Militaries and Militarization, Anthropology of

Andrew Bickford, George Mason University, Fairfax, VA, USA

Abstract

Anthropologists have become increasingly interested in militaries and militarization, as they recognize the role played by militaries, militarization, and warfare in culture and everyday life. By examining militarization and the military ethnographically, anthropologists analyze the methods and strategies used by state and military actors to influence, shape, and control perceptions of military service, military action, and military violence; how people respond, react, accept, and contest the military and militarization; and the ways in which military values and worldviews shape and influence culture, agency, and worldviews.

The end of the Cold War brought renewed hope for a reduction in militarization, a general demilitarization of global politics, and a long-awaited 'peace dividend.' Instead, the end of the Cold War resulted not in a diminishment of militarization in the United States and around the world, but an expansion of militarization and the influence of militaries in the form of prolonged wars in Iraq and Afghanistan, an expansion of US military power around the world via bases (see Gusterson, 2009; Lutz, 2009b; McCaffrey, 2002; Vine, 2009), the increased use of United States Special Operations Forces and drones in the 'War on Terror,'(Gusterson, 2011), the increased presence of the military and military values in everyday life (Ben-Ari, 2008, 2004; Feldman, 1994; Gusterson, 2007; Lutz, 2001, 2002, 2007), the skyrocketing of the US defense budget (see, for example Gonzalez, 2010; Gusterson, 2007, 2009; Lutz, 2001, 2002, 2007; The Network of Concerned Anthropologists, 2009), and discourses of 'heroism' and military superiority in the United States (Bickford, 2010) and elsewhere. Within this context of the increasingly visible expansion of the military in everyday life, the anthropology of militarization and the military has assumed a new importance, and a growing number of anthropologists now focus attention and research on the military and militarization, both in the United States and elsewhere. Once considered something of a 'niche' area of research, the study of militaries and militarization is an increasingly important specialization in contemporary anthropology.

As Max Weber contended, states claim a monopoly on 'legitimate' violence, and as sociologist Charles Tillly (1999) argued, war makes states. While war makes states, states need to make soldiers, lay the groundwork for support of the military and military action, and convince civilians to accept and to make war, thereby shaping and forming a key part of the political, cultural, and moral/ethical life of the state (Ben-Ari, 2004; Bickford, 2011; Gonzalez, 2010, 2009; Gusterson, 2007; Lutz, 2009a; Simons, 1999). Anthropologists who study militarization and the military concentrate upon the broad contours of these intersections. This is an important development in anthropology, as much of who, what, and where anthropologists have traditionally studied has been shaped or influenced by militarization and war in some way (see, for example, Green's work on war, violence, and trauma in Guatemala (1999) and the influence of decades of war and militarization on the Mayan widows she studied), and anthropologists have often been blind to or failed to see these connections between culture, militarization, and war (see Starn's (1991) critique of ethnographic research in Peru and the failure to recognize the Shining Path movement, and Hutchinson's work with the Nuer (1996) and her analysis of Evans-Pritchard's (1969) work with the Nuer in the 1930s).

While a large number of anthropologists have studied and theorized the origins of aggression and 'primitive' warfare, only fairly recently have an increasing number of anthropologists turned their gaze toward the military in the modern nation-state, and the impact of militarization policies on the cultures and life worlds of the people whom they study. Anthropologists have long been worried about the influence of the military and intelligence organizations on anthropological research (Boas, 1919; Price, 2008), but this concern did not necessarily translate into a focus on the military and militarization as objects of study for a variety of reasons. These reasons included access, a focus away from the nation-state, and political disdain: for a large number of anthropologists, the military as an object and site of study lay far outside their interests, both professionally and politically.

Once the seemingly exclusive purview of historians, political scientists, international relations specialists, and military sociologists, anthropologists have become increasingly interested in militaries and militarization, as they recognize the role played by militaries, militarization, and warfare in everyday life. Anthropologists who study the military and militarization often draw upon the work of militarization scholars from these other fields (political scientist Cynthia Enloe's work has been a major influence in anthropological studies of gender, militarization and militaries, for example), and in the process provide an ethnographic perspective and analysis that adds to and complements other analyses of militarization and the study of militaries. An approach that examines the socio-cultural-historical aspects of militarization allows for an examination of the ways in which preparations for war and military service influence and shape the identities, world views, and life courses of individuals, including how they cope with life in the civilian world after military service (Bickford, 2011: 24–25; see also Açiksöz, 2012; Finley, 2011; Gutmann and Lutz, 2010; Messinger, 2010; Wool and Messinger, 2012).

Anthropologists tend to focus on the 'lived experience' of militarization and the military in addition to its forms, structures, institutions, and content. The analysis of militarization policies and practices also provides a window into the ways state and military officials and actors work both in tandem and in contradiction to create the political structure of the 'State,' and to examine the practices and techniques of military power that state agents utilize in the consolidation of power and legitimacy. Anthropologists study the military in order to understand the impact of the military as an institution on those who are forced or volunteer to join and their families, the impact of the military on communities, and the physical, symbolic, and structural effects of military violence. By examining militarization and the military ethnographically, one sees the methods and strategies used by state and military actors to influence, shape, and control perceptions of military service, military action, and military violence; how people respond, react, accept, and contest the military and militarization; and the ways in which military values and worldviews linger on longer after encounters with militaries and militarization.

Defining Militarization

Broadly defined, militarization is the cultural, symbolic, and material preparation for war, and as recent research in anthropology has shown, militarization and the presence of state militaries influences much of the 'everyday life' in many societies and cultures around the world, both explicitly and subtly. Most importantly, militarization is an intentional process, something a state or group must set out to do; as Margaret Mead wrote, war – and in this case, the preparation for war – is not a 'biological necessity' (Mead, 1940). Rather, militarization and the development of military institutions are explicit projects, but are often cloaked in discourses of biological inevitability. Militarization programs often trade in and promote ideas about innate violence and the naturalness of military values (see Ferguson, 2009: 33–34; Fry, 2006, 2007); while sociobiological notions of 'natural' soldiers are politically convenient, these arguments sidestep analyses of power and process, and can be used to naturalize and depoliticize militarization processes and war (Bickford, 2011: 6–7; Ferguson, 2009; Fry, 2006, 2007) as a way to make them seem inevitable and irresistible.

Militarization draws from, and shapes, cultural contexts and histories and individual life courses. Broadly speaking, militarization is about the transformation of civilians into soldiers, and through the creation of certain types of soldiers, the creation of certain types of men and women; the creation of new types, conceptions, and understandings of 'citizens,' and the acceptance of these new types of categories and ways of being. It is a process of social, political, and military reproduction; the reproduction of the state through military values and identities; and the naturalization of the creative and (re)productive violence of the state in and through the very bodies of its citizens.

Anthropologists view militarization as a social process designed to bring about support for the military and shape social structures to support the military. Catherine Lutz's definition of militarization as "the shaping of national histories in ways that glorify and legitimate military action" (Lutz, 2007) is particularly useful in thinking through militarization programs, and the strategies necessary to implement a successful demilitarization program. Anthropologist Roberto Gonzalez, who, in his book *Militarizing Culture: Essays on the Warfare State*, examines the increasing militarization of the United States, draws from and expands historian Richard H. Kohn's definition of militarization, and the ways in which this relates to the ethnographic analysis of militarization:

> The degree to which a society's institutions, policies, behaviors, thought, and values are devoted to military power and shaped by war.
>
> Kohn, as cited in Gonzalez, 2010: 19

Lutz also describes militarization in terms of what she calls the 'military normal':

> The condition in which science, entertainment, business, and even high fashion deeply reflect militaristic values.
>
> Lutz, 2009a: 23–37

And Bickford (2011), in his analysis of East German militarization and the creation of 'soldiers,' examines how states attempt to create a 'military imaginary' in order to create a seemingly 'natural' bond between citizens and the military:

> The ways in which the necessity, implementation, and desired outcomes of (compulsory) military service and training are imagined and envisioned by the state, and the ways in which these tropes are linked to normative ideas of the "proper" soldier and [citizen], legitimate violence, morality, and military tradition.
>
> Bickford, 2011: 4

Militarization is about the transformation of civilians into soldiers, and through the creation of certain types of soldiers, the creation of certain types of men and citizens. It is also concerned with creating citizens who will support the creation and training of soldiers (Bickford, 2011; Gill, 1997). It is about making 'soldiering' and 'the military' appealing, and is concerned with garnering support for the military, military solutions, and military violence. Militarization is an exercise in attempting to establish hegemony through the promotion of military values, fear, and defense and of making these values seem natural, normal, and desirable (of course, in practice, this is not a smooth or entirely successful process, as evidenced by resistance to militarization, conscription, and war) (Bickford, 2011; others). A goal of militarization is to make people accept and love war, and see it as 'normal' (Lutz, 2009a). As anthropologist R. Brian Ferguson writes, "people have the capacity to learn, even to enjoy, war and build it into their social lives and institutions" (Ferguson, 2009: 34; Lutz, 2009a, 2007; see also Gonzalez, 2010: 27). Ferguson also notes that "Commentators have often compared war to a disease, but a more apt analogy is an addiction" (Ferguson, 2009: 40; see

also Gonzalez, 2010: 27). Militarization programs – and those who design and implement these programs – target and exploit this capacity to learn to love war. Indeed, people are supposed to learn to love war so much that they will willingly sacrifice their children for the state (Bickford, 2011; see also Perez's work (2006) on the militarization of Latina/o youth and the intersections of race and class in the United States). Ultimately, as anthropologists who work on militarization have shown, militarization is an idea – a deep-rooted insidious idea – that influences a large part of what constitutes the 'everyday' in modern states, and that makes the world make sense to many who internalize it as their own 'common sense' (see Lutz, 2009a, for her discussion of the 'military normal'; see also Herzfeld, 2001).

As anthropologists who study militarization and the military have shown, militarization programs depend on the establishment of deep networks within the state, and the deployment of discourses around courage, strength, honor, masculinity, femininity, credentials, health, marriage, violence, and identity. Militarization is not only about producing weapons and war materials but also about producing citizens, gender identities, family forms, language, ethics, morals, ways of being, and ways of seeing the world (Bickford, 2011; Cohn, 1987; Frühstuck, 2007; Gill, 1997, 2004; Gonzalez, 2010; Kanaaneh, 2005; Lutz, 2009a, 2007). Ultimately, militarization is a process that produces 'in-' and 'out-'groups, friends and enemies, the sacred and the profane, those who should be protected and those who should be killed, 'us' and 'them,' as well as 'we' and 'the other' (Bickford, 2011; Ferguson, 2009; Gonzalez, 2010; Gusterson, 2007; Mamdani, 2002; Waterston, 2009). Anthropologists who study militarization and the military engage many of these areas in their research, examining their overlapping influences and connections.

These definitions and perspectives make clear that military and militarized values will not simply disappear overnight, and that militarization impacts and influences a vast array of ideas, institutions, and processes that might seemingly appear far removed from traditional ideas about the military and war. Insights gleaned from anthropological work on militarization and militaries provide a necessary addition to military studies and a valuable complication to the analysis of demilitarization programs, showing that demilitarization needs to attend to the cultural side of war preparation, and not just to weapons and weapons systems. Militarization programs are also forms and visions of the state and the moral universe of the state in that they represent the ways and manners the state is imagined and desired, and that they shape 'permissible' and 'moral' forms of violence (Bickford, 2011: 24). In this sense, militarization programs are just as much about values and 'common sense' ideas about the world (see Herzfeld, 2001) as they are about producing tanks, planes, and land mines. States and military blocs create different rationales for different types of militaries, soldiers, and citizens. These competing visions contain different moral economies, which shape ideas about soldiering, killing, allegiance, human rights, conceptions of justice and law, and conceptions of political economy, and form the 'justification' for the use of military violence, rearmament, and the production of weapons.

Anthropology and Militaries

A key area of interest in the study of militarization is the study and analysis of militaries as institutions, and the influence of a 'military' on society, political economy, and everyday life. The majority of studies have focused on various aspects of the US military (see Bickford, 2010, 2008); Frese and Harrell, 2003; Gill, 2004; Gonzalez, 2010, 2009; MacLeish, 2013; Lutz, 2009a,b, 2007, 2002, 2001; Gutmann and Lutz, 2010; Finley, 2011; Simons (1997); Hautzinger and Scandlyn, 2013; Vine, 2009). However, anthropologists have also studied the armed forces of Japan (Frühstuck, 2007), Bolivia (Gill, 1997), Israel (Ben-Ari, 1998; Weiss, 2012; Kanaaneh, 2005), Canada (Irwin, 2011), and Germany (Bickford, 2011). These studies approach the study of militaries from a variety of angles, but with a number of overlapping themes, such as the production of 'the enemy'; the ways in which violence is legitimated, codified, and imagined; and the ways in which military service and gender intersect, just to name a few. In addition – and in conjunction with – the study of militarization, anthropologists also study the armed forces of a variety of states as a way to examine and often critique state power, violence, and military policies; the motivation for joining a military; the role of a military force in a state; and the effect of a military on the culture and daily life of a state. Irwin (2011) has studied the Canadian military and peacekeepers. Bickford (2011) examined both the East and West German militaries, and the German military after unification, focusing on militarization policies and the role of the military in the German Democratic Republic (GDR), the militarization of the GDR, and the policies and politics of memory in the German military after unification. Frühstuck (2007) has studied the Japanese Self-Defense Force, focusing on questions of militarization and gender in Japan, and the ways in which peacekeeping operations intersect with militarized masculinity. Frühstuck's ethnography is a fine-grained examination of military service, training, and militarized masculinity. Gill (1997) studied the intersections of citizenship, masculinity, and militarization in Bolivia. Gill also conducted research into the US Army's School of the Americas (SOA), and examined the militaries of United States and Central and South America, the ways in which the US military trained officers in brutal counterinsurgency tactics, and the politics of postatrocity impunity (2004). Ben-Ari (1998) studied the emotions and the construction of the 'enemy' in the Israeli army; Kanaaneh (2005) has studied Palestinian soldiers in the Israeli military; and Weiss (2012) studied conscientious objectors in the Israeli military.

Veterans

As anthropologists have increasingly engaged militarization and the military, they have also turned their attention to the experiences of soldiers and veterans as a way to examine the aftereffects of militarization, and the ways in which military service impacts daily life and life courses after military service or warfare. Anthropologists are also interested in the ways in which veterans and their experiences of military service are

coopted and used by the military for recruiting and propaganda purposes. Gutmann and Lutz (2010) write about and analyze the political awakening and activism of US military veterans of the wars in Iraq and Afghanistan, and how they have used their military experiences as a way to form political responses to militarization in the United States. Bickford (2011) conducted fieldwork with former members of the East German army and Border Guards, examining their experiences of dislocation and political estrangement after German unification, and the ways in which East German militarization impacted their decisions to become career officers. Carbonella (2003) writes about the connections between representations of Vietnam veterans and globalization, and Wagner (2013) and Wagner and Quintyn (2009) write about the Tomb of the Unknown Soldier in the United States, and the politics of veterans, war dead, and commemoration in the United States.

Health and Technology

Anthropologists are also increasingly interested in the intersections of militarization, war, health, and medicine, and ways in which both civilians and soldiers experience war and the preparation for warfare in terms of bodily experience, illness, wounding, and as a biomedical project concerned with battlefield performance enhancement. This research overlaps with the study of veterans; indeed, many anthropologists who study veterans are also keenly interested in experiences and narratives of veterans' trauma and suffering. Messinger (2010) and Wool and Messinger (2012) study US military personnel who suffered amputations, and how they come to terms with new prosthetic limbs. Açiksöz (2012) studies nationalism, masculinity, and the political identity of Turkish Army soldiers who lost limbs fighting the Kurdish Workers Party (Partiya Karkerên Kurdistan (PKK)). Finley (2011) and Hautzinger and Scandlyn (2013) study posttraumatic stress disorder among US combat veterans; and Vasquez (2009) explores visual technologies and soldiers' experiences of warfare. Bickford (2008) studies advances in US military medicine and the militarization of medicine in the production of 'super soldiers' in the United States. Wagner (2008) has conducted extensive research into the use of deoxyribonucleic acid analysis to identify and recover genocide victims in Bosnia, and the ways in which veterans, survivors, and their families come to terms with war and genocide in Bosnia. Also, Russ and Ames (2006) examined competing policies and practices on health and sexuality in the US Navy.

Counterinsurgency, Militarization, and Anthropology

Directly related to the study of militarization and militaries is one of the most contentious debates in recent anthropology: anthropology's relationship to the military, and the US military's attempts to utilize anthropology as a kind of 'force multiplier' in counterinsurgency operations in Iraq, Afghanistan, and elsewhere. While anthropology has had a long history of some forms of collaboration with the military (see Price, 2011, 2008, 2004), and resistance to the military's use of anthropology (Boas, 1919; Network of Concerned Anthropologists, 2009; Price, 2011), the recent controversy surrounding the US military's 'Human Terrain System' and the embedding of anthropologists and other social scientists in military units (with anthropologists wearing uniforms and in some instances carrying weapons) brought this relationship once again to the forefront as an ethical issue within the American Anthropological Association. Some anthropologists have spoken out against the military use of anthropology, arguing that the US military is attempting to militarize and 'weaponize' anthropology (Forte, 2011; Gonzalez, 2009; The Network of Concerned Anthropologists, 2009; Price, 2011), while others argue that anthropology should work with and engage the military as a way to provide the military with cultural knowledge and training in order to reduce violence and military action (Albro, Marcus, McNamara, and Schoch-Spana, eds. 2012; Fosher, 2011; McFate, 2005; McFate and Fondacaro, 2011; Rubenstein et al., 2012; Selmeski, 2007). In 2007, the American Anthropological Association commissioned a report investigating the controversy, and concluded that anthropologists need to follow ethical fieldwork practices, regardless of which side of the debate they are on.

Recent works that examine the controversy around anthropology, counterinsurgency, and anthropology's relationship to the state and military include Schaft's (2007) examination of anthropology in Nazi Germany, Bahn's work on counterinsurgency in India (2013), Gonzalez's overview of American counterinsurgency programs and anthropology (2009), McNamara and Rubinstein's (eds.) edited volume examining both sides of the counterinsurgency and anthropology controversy (2011), and Kelly, Jauregui, Mitchell, and Walton's (eds.) volume examining counterinsurgency programs around the world (2010). Wakin (1992) writes about anthropology, counterinsurgency, and Thailand, and David Price (Price, 2011, 2008, 2004) has written extensively about the relationship(s) between anthropology, the military, and intelligence agencies (Price, 2011, 2008).

Anthropology of Bases

One recent direction in the anthropology of militaries and militarization is an analysis of the impact of US military bases around the world and in the United States, and the experiences of those who live on, work on, or who have been displaced by military bases. McCaffrey examined the US Navy's use of the Puerto Rican island of Vieques as a bombing range, and the subsequent protest movements to dislodge the US military from the island (2002). Vine, in *Island of Shame*, examined the impact of the US/UK base on Diego Garcia in the Indian Ocean, and the forced relocation of the island's original inhabitants (2009). Vine has also written about the increase of US bases around the world (2012). Lutz (2009b) conducted an in-depth analysis of the impact of Fort Bragg on the city of Fayetteville, North Carolina, and MacLeish (2013) conducted fieldwork with soldiers and civilians at Fort Hood, a major US Army base in Texas. Gill (2004) conducted extensive fieldwork at the US Army's 'SOA,' at Fort Benning, Georgia. Besteman (2009, 2008) and Vine (2012) have examined

the US military's 'Africa Command' (AFRICOM), and the proliferation of US military bases in Africa. Gusterson (1996) and Masco (2006) have both examined nuclear weapons research and research laboratories and their impact on communities in California and New Mexico.

Anthropology, Militarization, and Demilitarization

While the turn toward research on militarization and militaries is an important step in anthropology, the logical next step is to draw from and expand research on militarization and militaries, and to engage ethnographically with demilitarization, and the ways in which states and groups come to terms with the end of militarization programs and the lingering aftereffects of militarization. A discussion of recent work in anthropology on militarization points toward a discussion of demilitarization, and how people come to terms with the lingering effects and impacts of militarization, war, and violence. If militarization depends on the creation of dense networks of 'positive' feelings toward the military, for instance, how exactly does one come to terms with these networks after a militarization program ends, after a war, or after military violence? How do people 'unravel' or dismantle militarization programs? How do people come to terms with the effects of militaries, militarization, and war? Demilitarization implies a reversal of an implicit process or program, an unraveling, an unmaking, of that which came before and of ways of thinking, feeling, and seeing that made a military solution thinkable and desirable (Bickford, 2013). As anthropologists have shown, militarization can be a pervasive and deeply woven thread in a culture (see Green, 1999); to unravel it or do away with it requires a thorough understanding of how militarization works.

Demilitarization is often narrowly defined as simply the dismantling or demobilization of a military, and the eventual destruction of military equipment, the destruction of weapons and explosives, and the incineration and destruction of chemical and biological weapons. Of course, these are important steps in demilitarization, but they can also be seen as merely the 'surface' level of a demilitarization program. If militarization is about shaping and creating a populace that either embraces, or at least goes along with, positive ideas and values associated with war and killing, then simply destroying weapons after the fact is not enough to effectively demilitarize a society. Narrow definitions of demilitarization centered solely on weapons obscure analysis of the social relations and cultural constructions of militarization. As Bickford (2013, 2011), Açiksöz (2012), Gutmann and Lutz (2010), and Carbonella (2003) have shown in their studies of military veterans, enculturation into military norms and worldviews does not go away overnight; these experiences and 'training' linger on, shaping how people see and think for years afterward.

Anthropologists have examined aspects of demilitarization and the aftereffects of warfare and violence. As Hinton (2002) argues in his overview of the anthropology of genocide, there is a need to attend to local dimensions and experiences of war and genocide in order to understand how war and genocide took the form(s) they did (see, for example, Bahn, 2013; Besteman, 1999; Gill, 2009; Green, 1999; Hinton, 2002, 2004; Hoffman, 2005; Malkki, 1995; Manz, 2009; Nordstrom, 2009, 2004; Olujic, 1998; Robben, 1995; Schaft, 2007; Wagner, 2008). In other words, one needs to understand the cultural forms that obtain in a given situation, and how they shape and mediate expressions of militarization, war, and violence in order to develop demilitarization strategies that can attend to underlying cultural logics and issues; without this, there is a risk of merely attending to the 'surface' level of violence and failing to understand how deeply rooted and entrenched militarization and the creation of the 'military normal' (Lutz, 2009a) can be. Demilitarization can also entail a process of accountability, of trying those responsible for militarization, war, genocide, and atrocities accountable for their actions, such as the Nuremberg trials after World War II, the Truth and Reconciliation Commission(s) in South Africa and Rwanda, and the Enquete Commission in Germany after unification (see Bickford, 2011; Hinton, 2002; Scheper-Hughes and Bourgois, 2004; Wagner, 2008; Waterston, 2009).

Anthropological studies of militarization and militaries shed light on the programs, formations, and processes of violence in the state, and can inform analysis and discussions of demilitarization programs, as they make explicit the often unstated or hidden assumptions, desires, and forms of power that make them effective and deeply entrenched. Coming to terms with militarization, militaries, and war, and thinking through demilitarization programs compel us to think not only about disarmament and the destruction of weapons but also about the sociocultural aspects of militarization. Insights from the anthropology of militarization and militaries demonstrate that to fully understand militarization, and to possibly demilitarize a society, there is a need to take into account the connections anthropologists have found between militarization and gender, sexuality, language, education, race, class, age, ideology, health, identity, status, honor, shame, heroism, 'soldiers,' veterans, sacrifice, media, entertainment, esthetics, families, development, globalization, military bases at home and abroad, science, religion, the state, the nation, space, place, the 'other,' and perhaps, most importantly, how individuals think about all these, and create identities and worldviews shaped by and through militarization and militaries.

Militarism

Anna Stavrianakis, University of Sussex, Brighton, UK

© 2015 Elsevier Ltd. All rights reserved.

Abstract

The concept of militarism has had an ambivalent status in the social sciences, veering between polemic and analytical usage. This article seeks to clear the ground by outlining five main definitions of militarism, as: an ideology glorifying war; the propensity to use force; military buildup; excessive influence (of either the institution of the military or of the military–industrial complex); and the influence of military relations on social relations in general. It then discusses the modernist tilt to much of the discussion and questions of methodological nationalism and the appropriate scale of analysis. Finally, it addresses some of the normative issues around the study of militarism.

Introduction

Militarism has an ambivalent status as a social science concept. Subject to varying definitions, conceptualizations and approaches within and between disciplines, its usage has veered between pejorative polemic and social scientific analysis, and it has experienced peaks and troughs in academic discourse according to international and historical conjuncture. While war and military power have a much longer history, both as practices and as objects of analysis, the academic study of militarism took off in the late nineteenth century, becoming particularly prominent in relation to Germany in the context of World War I (WWI). Since then, the production of knowledge about militarism has both shaped, and been shaped by, the practice of war, war preparation, and military power itself. The various definitions and trends in the study of militarism morph as the practice of war, and the exercise of power in international politics, changes.

Others have provided chronological accounts of the debate over militarism (e.g., Berghahn, 1981; Bucholz, 1999). In what follows, I provide a fivefold set of definitions of militarism that crosses some of the chronological and theoretical boundaries that typify debate. Militarism can variously be understood as: an ideology glorifying war; the propensity to use force; military buildup; excessive influence (of either the institution of the military or of the military–industrial complex (MIC)); or the influence of military relations on social relations in general. These definitions become progressively more sociological: for example, the use of force may not rest on outright glorification of war and may draw on other sources of social power; military buildup can occur in scenarios without the direct of military force; and the military can exercise influence even when it does not seize power directly through a coup. I then discuss two key issues that cut across these definitions and shape the overall debate around militarism, namely the modernist tilt to much of the discussion, and questions of methodological nationalism and the appropriate scale of analysis. Finally, in conclusion I address some of the normative issues around the study of militarism.

Definitions and Approaches

Militarism as Ideology

Historically, militarism has been widely understood as an ideology that glorifies war, military institutions, and martial values. A 'powerful war mythology' took hold in Europe in the decades prior to 1914, emphasizing elite and noble values, honor, courage, duty, and patriotism (Bucholz, 1999: 426–427), with militarism assuming 'the importance of a basic cultural value' in WWI Germany (Berghahn, 1981: 32). Outside of Europe, scholars have emphasized the spiritual and ideological dimensions of late nineteenth- and early twentieth-century Japanese militarism seen through concepts such as *bushido*, the way of the warrior or samurai (Bucholz, 1999: 427). Alfred Vagts later made the distinction between the rational and effective 'military way' in the conduct of war, and militarism: that "complex of feelings which rank military institutions and ways above the ways of civilian life, carrying military mentality and modes of acting and decision into the civilian sphere." For him, militarism was characterized by "qualities of caste and cult, authority and belief," and involved "an emphasis on military considerations, spirit, ideals, and scales of value, in the life of states" (Vagts, 1959: 13–17).

Ideological definitions are now rather rare, both because militarism itself is rarely a primarily ideological phenomenon, and also because definitions based on ideology are analytically inadequate. The outright valorization of war and state militaries is now less prevalent: the social conditions that facilitated the mass ideological mobilization of the early to mid-twentieth century have changed. Societal mobilization for and justification of war depend on more than glorification, and take a variety of forms in different societies and across time. As Shaw puts it, "[i]t is sociologically unenlightening to restrict the meaning to ideology: the core idea is the 'carrying' of military forms into the civilian sphere," which requires analysis of practices as well as mentalities and attitudes. In addition, these military forms may justify war and military power without actively glorifying them (Shaw, 2013: 19–20). War and war preparation have not gone away, but they are created, perpetuated, and justified in different ways. While an ideological dimension remains important in various contemporary scholarly debates, with historical sociologists such as Michael

Mann and feminists such as Cynthia Enloe emphasizing the attitudes, values, and beliefs that characterize militarism (Mann, 1987: 71; Enloe, 1988: 7), they embed this dimension of militarism in more sociological accounts that emphasize material as well as ideational context, and move beyond the immediate glorification of war and military institutions.

Militarism as the Use of Force to Resolve Conflict

A second type of definition is behavioral: militarism as the propensity to utilize force to resolve conflict. For structural realists in International Relations, for example, militarism explains those instances where great powers act in nonstrategic ways. Militarism is an aberration in an anarchic international system, in which the use of force is the ultimate arbiter (Van Evera, cited in Mearsheimer, 2010: 84). Eide and Thee, meanwhile, working in the peace research tradition, define militarization as "the inclination to rely on military means of coercion for the handling of conflicts" (1980: 9). Such a tradition has continued in the post-Cold War peace research agenda on "Militarized Interstate Disputes," which studies the threat, display, or use of force by states against each other (Correlates of War, n.d.). For others, meanwhile, militarism as the use of force is not restricted to interstate relations: some focus on the domestic use of force against recalcitrant populations. For many Marxists, militarism has a dual aspect, being exercised against internal as well as external enemies to promote the expansion of capitalist power outside the territorial confines of the nation-state, and the maintenance of order within the nation-state (e.g., Liebknecht, 1973).

For all their differences, behavioral approaches do not assume that a propensity to use force is necessarily or essentially rooted in martial values or the glorification of war. The emphasis on behavior, however, focuses on the directly observable use of force while downplaying the political or sociological processes underlying not only war but military power more generally. As Skjelsbaek argues, while militarist behavior, "the excess use of violence" or "the actual use of an excessive military apparatus in war," is in some ways the most direct, central, and observable dimension of militarism, this underplays the latent use of weapons, social structures, ideology, strain on the economy of military spending, and so on (Skjelsbæk, 1980: 87). That is, militarism draws upon numerous sources for its power and legitimacy, not just on acts of violence, and can remain entrenched even in relatively pacific (at least international) contexts. Behavioral definitions are thus rather narrow, relying on directly observable phenomena, underplaying the wider role of military power in society.

Militarism as Military Buildup

A third definition is of militarism as military buildup, in particular, quantitative increases in weapons production and imports, military personnel, and military expenditure. This concern was shared by both strategic studies and peace research scholars during the Cold War, despite their different research focus and politics. Strategists were more interested in superpower nuclear rivalry, deterrence, arms racing, action–reaction models, and so on, while peace researchers were concerned about spiraling military spending and the transfer of weapons to the South. Ross, for instance, understands and measures militarism by six indicators: levels of military expenditure, arms imports, and arms production; size of armed forces; and number of wars and military regimes (Ross, 1987). This type of definition survived the end of the Cold War and continues to be prominent in both research agendas. In contemporary peace research, a predilection for statistical analysis has meshed with post-Cold War concerns around liberal democracy, trade liberalization, ethnicity, and so on in assessing the likelihood of militarization. And in contemporary strategic studies, such quantitative accounting of military forces and equipment forms the bedrock of analyses of the military balance of power and likely outbreak of war.

This type of work lends quantitative robustness to the study of militarism, allowing for the identification of patterns and thus comparison. However, in a similar vein to behavioral definitions, what remains unaddressed is the social embeddedness, power, or meanings of militarism, or those social, political, and international structures and processes in which military buildups are so powerfully rooted (for a critique of the thinness of this 'militarization thesis,' see Shaw, 1991: 66–73). A more sociological account of military buildup can be seen in Kaldor's Cold War-era work on the increasingly 'baroque' character of modern military technology (Kaldor, 1982a), grounding military production in political economy; and in E.P. Thompson's critique of the ideology of exterminism that of which the superpower nuclear arms race was a symptom (Thompson, 1982).

Militarism as Excessive Influence

A fourth definition is of militarism as the excessive influence of either the institution of the state military or of the MIC. The former is characteristic of a civil–military relations approach, of which there are various strands. These include a US-focused literature on the rise of a standing army post-WWII (e.g., Lasswell, 1950; Huntington, 1957; Janowitz, 1960); and the Cold War concern with the role of the military as a potential modernizing force in so-called 'new nations' (e.g., Huntington, 1968; Janowitz, 1977; Pye, 1962). The literature on the developing world initially mostly focused on coups, but later shifted to a broader spectrum of military influence, because of the observation that the military can be powerful even if it does not seize power directly.

There is debate as to whether it is the characteristics of the military itself, or society, that are the more important variable in understanding militarism. However, the civil–military relations approach as a whole rests on the problematic idea of an 'equation,' with the military on one side and civilian institutions and procedures on the other (Valenzuela, 1985). But the civilian side is not just another institution; the military is an actor within a social and political system, not a neutral force outside its boundaries. The two 'sides' are thus highly interpenetrated. Civil–military relations discussions of militarism – in which militarism occurs when the 'balance' tilts too far in favor of the military – are thus limited by a conceptual separation between military and society that obscures the grounding of military power in social relations.

Literature on the MIC starts to overcome this pluralist separation between the military and civilian institutions, focusing

instead on the shared interests between the military, military industry, top-level government bureaucrats, and legislators and the influence they exercise on society as a whole. This type of approach is more focused on the socioeconomic dimensions of militarism, as compared to the institutional approach of the civil–military relations literature. There are a variety of theoretical perspectives in play, but the result of these relationships is variously characterized as coordinated and mutually supportive influence that creates a shared interest in continued military spending (Rosen, 1973: 2–3), "a set of commonly shared interests between the military and some major corporations" (Lieberson, 1973: 61), and a "self-serving accommodation between corporate elites, government bureaucrats, and the military hierarchy" (Moskos, 1972: 4).

The civil–military relations and MIC approaches are both useful ways in two particular aspects of militarism – the institutional and the political-economic. But the focus on either institutions or economic relations cannot adequately explain militarism in its broader sense of the preparation for and conduct of organized political violence. In addition, both approaches tend to be nationally based in their explanations. MIC accounts are useful for thinking about the political economy of militarism, and thus start to ground militarism in social relations (e.g., between arms companies, politicians, and the military); but usually remain focused on national economies, which is problematic given the internationalization of military industry. And civil–military relations approaches have tended to assume a sovereign nation-state, which is problematic given the internationalization of military power through alliances, foreign military training, arms transfers, and so on. These processes challenge the basic assumption that the key explanatory variables (military and domestic political process) are located within national societies (Valenzuela, 1985).

Militarism as the Influence of Military Relations on Social Relations

The definitions discussed thus far have each provided insights into particular dimensions of militarism; yet they tend to lack sociological depth. That is the impetus to the fifth definition provided here, that of militarism as the influence of military relations on social relations. In this, the component parts of other definitions – ideology, military buildup, institutional relations, and so on – are understood as embedded in society. It is this wider social context that is crucial for understanding the way that not only war, but also war preparation and military power, are produced, reproduced, and, at times, challenged. As Martin Shaw defines it, militarism is "the penetration of social relations in general by military relations" or the "relationship of war preparation and society" (Shaw, 1991, 2013: 9–15). Sociological approaches can be inflected in a variety of ways theoretically, from the neo-Weberian historical sociology of Shaw and Michael Mann, to the Marxism of Mary Kaldor's Cold War work on the mode of warfare (1982b) and feminist sociologies of the mutually constitutive relations between militarism and patriarchy (e.g., Cock, 1991; Enloe, 1988).

This is a much more abstract definition, the empirical content of which depends on the case under analysis. In contrast to most approaches, which see militarism as an end-state, and militarization as the process through which it is reached, militarism here is an abstraction rather than a phenomenon. That is, the concept of 'military' is used not as a noun to refer to an institution, but to describe "all social relations, institutions and values relating to war and war preparation" (Shaw, 2003: 106); and militar*ism*, in turn, is understood as the tendency or extent to which these military relations influence social relations as a whole. Militarization and demilitarization can be measured and their character assessed: as military relations exercise greater influence on social relations in general, militarization increases, and vice versa. This approach is more open analytically, in terms of the scale at which militarism is to be studied, and the normative ramifications of analysis. Before addressing this, I turn first to the prior question of the relationship of militarism to modernity, which shapes much of the debate.

Militarism and Modernity

While war and military power, and the study thereof, obviously have a much longer history, the concept and academic study of militarism is a modern phenomenon, emerging in the nineteenth century (Berghahn, 1981: 7). And there is something specific about modern militarism: Vagts' general definition of militarism as 'a tendency to extend dominion,' which is more clearly transhistorical, is qualified by the specificity of modern militarism, in which militaries are not constantly engaged in combat, so they become narcissistic (Berghahn, 1981: 38–39). Much social science discussion is marked by a similarly distinctively modernist orientation. Despite the significant differences between them, liberal and Marxist discussions share the idea of historical progress and development leading to the withering of militarism (Shaw, 1991: 15–17). Classical liberals believed that militarism would die out with the industrialization and modernization associated with the development of capitalism, as seen in Herbert Spencer's distinction between militant and industrial society, for example. For Marxists, while many saw capitalism as militaristic, they still anticipated that the transition to communism would mean militarism died out. Social theory, itself a child of modernity, has long held militarism to be a throwback to a more violent past, one that will be exorcised through progress and development.

This logic of progress was evident in discussions of Prusso-German and Japanese militarism, revolving around the relationship between 'backwardness' and the transition from agrarian to industrial society; whether these should be considered similar or different cases in terms of their levels of capitalist development and industrialization; and the distinction from the more 'advanced' West. Part of this was also about allowing Anglo-Saxon liberals to refute the Marxist critique that Western capitalist-industrial societies were necessarily militaristic (Berghahn, 1981: 67, 120). The logic of progress is also clearly seen in discussions of the military as a modernizing agent in the Third World. The emergence of this literature was part of the growth of a comparative politics approach in political science, which featured the rise of structural-functional schemes and social systems metaphors (Valenzuela, 1985: 133). The context of the

modernization debate is evolutionary theories of society and the effort to ensure Third World countries become capitalist-industrial societies, with free market economies, parliamentary-democratic institutions, and industrialization (Berghahn, 1981: 71).

This modernist belief has been challenged from various quarters, however. Not only is there a marginalized 'bellicose tradition' in older continental European social theory (Malesevic, 2010), but contemporary historical sociologists have attempted to shatter "the dream of a modernity without violence" (Joas, 2003). In particular, there is a strand of scholarship that emphasizes the autonomy of war and militarism as social forces in their own right (Shaw, 1988; Barkawi, 2011) rather than an expression or symptom of either geopolitics or capitalism. Feminist and postcolonial scholars have also troubled the notion that militarism is a remnant of a more violent past. Gender roles in war are consistent across space and time (despite the diversity of gender and war separately) (Goldstein, 2006: 3) and militarism relies on particular forms of masculinities in societies "with otherwise dissimilar cultures and uneven levels of industrialisation" (Enloe, 1993: 72–73). Crucially, these are also racialized as well as gendered. Bell Hooks emphasizes not only "the contradiction that black men should serve in wars, die for this country, for this democracy, which institutionalized racism and denied them freedom" (1995: 58–59), but also that "Black women are very likely to feel strongly that white women have been quite violent, militaristic in their support and maintenance of racism" (Hooks, 1995: 59–60). As other postcolonial scholars remind us, from the periphery, modernity has never looked pacific (Krishna, 2001).

Scale of Analysis

Discussions of the relationship of militarism to geopolitics, capitalism, and patriarchy raise methodological questions around the scale at which militarism is studied. Many studies of militarism – despite different conceptual and theoretical premises – use an essentially statist or methodologically nationalist framework for studying militarism, especially in country case studies, studies of civil–military relations, and also quantitative analyses which compare different levels of militarization between states. Others, by contrast, are implicitly or explicitly critical of such state-centrism, emphasizing instead the ways, in which militarism is structured by, or embedded within, transnational, imperial, or global social relations. Thee, for example, distinguishes between the outward-oriented militarism of great powers and the inward-oriented militarism of developing countries governed by military regimes, arguing that the former is "also largely the root cause and the driving force behind the global spread of militarism" (Thee, 1980: 21–24). Militarism as a global phenomenon is thus shaped by relations between core and periphery. Scholars of various persuasions have tackled this, from the structural arguments of Cold War peace researchers to identity-based arguments of post-Cold War constructivists.

Scholars working in more anthropological and sociological traditions, meanwhile, have scaled down the study of militarism to specific sites and to questions of subjectivity. Feminist analyses have demonstrated that both liberal and Marxist approaches may have "dramatically *under*estimated the power it requires to militarize any society" (Enloe, 1993: 51). This draws our attention to the societal level and everyday scale in order to understand both the impact of war and militarism on people (especially, but not only, women) as well as the gendered construction of war and militarism (Sjoberg and Via, 2010: 231–232).

It is not a question of 'choosing' an appropriate level – be it international, national, or subnational – however. As Sjoberg and Via put it, "absolutely distinguishing between the personal, national and international level of war and militarism lacks conceptual and empirical rigor at best" (2010: 233–234) as the so-called 'levels' are interdependent. The various 'levels of analysis' need to be considered in co-constitutive interaction (Stavrianakis and Selby, 2013a: 15): militarism at any scale is shot through with international relations, and any macro analysis needs to take social relations into account.

Conclusion

Militarism has an ambiguous status as a social science concept, deriving at least in part from its polemic or pejorative overtones (Shaw, 2013: 19): militarism is often an accusation rather than an analysis. In addition to the sometimes problematic ways the concept itself has been used, the wider intellectual climate has been more or less hospitable to discussions of militarism over time. For example, the post-Cold War political and intellectual hegemony of liberalism, the rise of influential and policy-related discourses on 'failed states' and 'new wars,' and the dominance of discussions of 'security' and 'securitization' have all contributed to the marginalization of militarism as a key concept in International Relations (Stavrianakis and Selby, 2013a: 6). Despite this, the concept has a rich and varied history, as the various definitions have shown; and across the social sciences it is still in play, often in rich and innovative ways.

Much scholarship on militarism is informed by some degree or form of antimilitarism – whether it be criticism of the excessive buildup of military capabilities, a critique of military power per se and its relationship to capitalism, or opposition to the gendered ways in which men and women are incorporated into war practices. The possibility for opposition to militarism depends on both the character of militarism itself in any given place and time, as well as on wider socioeconomic, political, and cultural patterns (Shaw, 2013). For others, an oppositional politics of antimilitarism is replaced by a politics of 'countermilitarism.' This involves responding to the diffuse character of contemporary military power with broader forms of critical engagement beyond simple opposition, such as dialogue, subversion, and mimicry (Stavrianakis and Selby, 2013b). And critical intellectual positions do not map easily on to political persuasions – conservative critics of US foreign policy have resurrected the language of militarism in relation to the wars in Iraq and Afghanistan (e.g., Bacevich, 2005). Such differences speak to the various ways that political and intellectual sensibilities intersect.

To be sure, the normative issues around militarism are not clear-cut. There is plenty of contemporary empirical evidence of

practices we may want to associate with militarism, such as the recent and ongoing wars in Afghanistan, Sudan, Libya, Syria, and elsewhere; rising military spending under the rubric of the War on Terror; and military coups in Mali, Niger, Thailand, Honduras, and elsewhere. But their causes, meaning, and relative significance are disputed. To take just two examples: liberal wars of intervention under the guise of humanitarianism and liberation have occurred in a context of structural demilitarization of Western societies and economies since the end of WWII. So force can still be deployed outward while domestic society is less obviously militarized – perhaps even more so because of the growing separation of the military from society and its professionalization. And liberal equality agendas within some national militaries are widely seen as progressive in terms of the rights of women, homosexuals, and ethnic minorities. Yet they simultaneously reinforce militarism by incorporating marginalized parts of the population into war fighting and war preparation. These examples suggest the need for an ongoing discussion about militarism, to which conceptual clarity can make a significant contribution.

Abstract

Military and disaster psychiatrists assist both trauma-exposed people and organizations who have experienced extreme circumstances that have the potential to damage mental health and impair organizational, community, and individual functioning. While most trauma-exposed individuals remain psychologically healthy in the longer term, there is a strong evidence base showing that high-quality social support and experiencing a low, but not no, pressure environment are the most ideal conditions to support recovery. Ensuring that basic needs such as provision of shelter and food are met are also important perquisites to a good state of post-conflict or post-disaster mental health.

Individuals exposed to traumatic events are at increased risk of suffering from a range of mental health conditions including, but not limited to, posttraumatic stress disorder (PTSD; NICE, 2005). While the definition of a traumatic event has changed as new evidence has emerged, our current understanding includes a potential to affect people who are directly or indirectly exposed to an event as well as those who indirectly learn of a close relative/friend's trauma. Importantly, current diagnostic guidelines specifically acknowledge that PTSD may follow repeated or extreme indirect exposure to aversive details of events that occur in the course of professional duties (APA, 2013). This criterion specifically acknowledges that some workers are at particular, and predictable, risk of developing trauma-related mental health problems as function of their employment. Indeed, there is a wealth of evidence that as well the innocent victims of disasters, many occupational groups, including military personnel and emergency services personnel, are in substantially higher levels of trauma-related psychopathology than the general population (Skogstad et al., 2013).

Military and disaster psychiatry has evolved to take account of the cognitive, emotional, and potential neurobehavioral consequences of trauma exposure including human-made events (e.g., wars and terrorist attacks) and natural disasters (e.g., earthquakes or accidents). Mental health care interventions in military operations, and in response to disasters, generally follow a preventative medicine approach. That is to say that the most ideal occurrence is for individuals to avoid the development of mental health difficulties after exposure to traumatic events (primary prevention); where impairing symptoms do develop it is best to detect incipient mental health problems rapidly so that effective early intervention can be provided (secondary prevention); and where individuals do go on to develop formal mental health conditions, then evidence-based treatment should be provided in a culturally-sensitive manner by appropriate trained and experienced mental health professionals (tertiary prevention). Providing an evidence-based preventative approach to the prevention of traumatic stress related conditions is likely to be a legal responsibility for trauma-exposed organizations, such as the military, media companies, war correspondents, or emergency responders (UKPTS, 2014). However, the responsibility for protecting the mental health of individuals involved in disasters is less clear and the delivery of disaster psychiatry is often a result of a complex interplay of agencies including regular health care providers, local charities, nongovernmental organizations (NGOs), and local members of the community who 'pull together' in the aftermath of an incident.

Mental health care interventions delivered in theaters of war or within disaster zones are likely to differ from those delivered in traditional community- or hospital-based practice. This article examines the approaches of military and disaster psychiatry, and the cognitive, emotional, and behavioral responses associated with the events that create these environments. The principles of prevention, detection, and treatment of posttraumatic illness on the battlefield and in the aftermath of disaster are outlined. Finally, emerging cultural, ethical, and possible future technological challenges to the practice of military and disaster psychiatry are discussed.

Introduction

Both war and disaster have the potential to create an atmosphere of chaos and tragedy. Individuals who operate in these environments may experience both expected stressors, such as seeing dead bodies, and the effects of injuries in local population, and potentially among colleagues, and also a range of less predictable pressures such as being called on to make rapid decisions that have the capacity to expose individuals to moral insult or injury. For instance, individuals may be forced to choose to save their own life at the expense of someone else losing theirs. However, there is considerable evidence that while exposure to traumatic stressors may be inevitable, personnel appropriately prepared or trained to operate in these environments, may be less at risk of psychological injury than those who simply caught up in the chaotic nature of war or disaster (Rubin et al., 2005). Military and disaster psychiatry professionals have to address care demands in, or resulting from, working within nontraditional environments and in mass casualty situations, where resources are overwhelmed. Providing care in such environments is multi-professional relying on contributions of psychiatrists, mental health nurses, psychologists and social workers, other health care

workers, social scientists, epidemiologists, and emergency responders such as police and firemen. There is growing evidence that the psychological resilience of teams that operate in these environments (e.g., military forces, charitable organizations, and media) is more a function of the bonds between individuals (i.e., camaraderie and leadership) between team members than the psychological coping styles of the individuals concerned (Jones et al., 2012).

Any overview of military and disaster psychiatry begins with an examination of the consequences of traumatic situations such as disasters and wars for communities, and individuals, the provision of health and health care responses to these traumatic experiences.

The War and Disaster Environment

Disasters have the capacity to overwhelm a community's capacity to respond to them. The distinction between 'natural' disasters (e.g., earthquakes) and human-made, or technological ones, such as explosions, or train derailments, has become increasingly difficult to make. For example, much of the death and destruction from an earthquake may be due to poorly constructed housing or the failure of emergency services to respond in a timely and effective fashion. Thus, the vast majority of disasters have at least some human element to them particularly in terms of those who are affected and in the response. For example, communities may blame governments or commercial companies for failing to respond to a traumatic event in a timely and effective manner even where an incident was truly unforeseeable. From a psychological standpoint, it may be helpful to understand the inevitability, and impact, of the blame by those affected by the disaster toward statutory authorities (e.g., councils, governments, and emergency responders). In the main, blame, however well placed, impedes psychological recovery of those affected by an event.

Potential stressors in disaster environments include exposure to the dead or injured, threats to life, loss of loved ones or property, and/or physical injury. Although military forces, when commanded to do so, assist affected communities and provide a relatively safe environment for those affected by traumatic events, such safety may often be short lived.

Frequently, those so affected by war or disasters are reluctant to seek help for mental health difficulties (Osório et al., 2013), and thus do not receive treatment for psychiatric symptoms. Although traumatic events themselves can be short lived, for example, an earthquake may be concluded in seconds, the consequential traumatic experiences may continue for weeks or months and, if not managed well or treated, possibly years. For both military personnel and civilians in war or on-going disasters environments, exposure over time may include anticipated or entirely unexpected life-threatening experiences followed by daily life in an austere and disrupted environment.

In very general terms, post-disaster emotional and behavioral responses occur in four broad phases. The first, immediately following a disaster, consists of strong emotions including feelings of disbelief, numbness, fear, and confusion for those involved with the event; all are quite normal emotional responses to abnormal events. The second phase, which usually lasts from a week to several months, is accompanied by the appearance of assistance from outside agencies and communities. Adaptation to austere environments as well as intrusive symptoms (unbidden thoughts and feelings accompanied by hyperarousal) occur during this phase and physical (somatic) symptoms such as fatigue, dizziness, headaches, and nausea may develop. Anger, irritability, apathy, and social withdrawal are often present, and these cognitive and emotional responses may be misplaced. For instance, those affected by the incident(s) may begin to feel resentful or angry toward those who they perceive as having responsibility for responding to the incident. The third phase of a trauma response is often marked by increased feelings of disappointment and resentment when hopes for aid and restoration are not met. These feelings may lead to the sense of community being weakened as individuals increasingly focus on their personal needs rather than the needs of the community. The final phase, which is termed reconstruction, may last for years. During this period, people rebuild their lives, make homes and find work using available social supports. Individuals may progress through these phases at various rates. Failure to navigate through this reconstructive phase can lead to persistent symptoms.

While PTSD is a relatively new diagnosis, first appearing in the Diagnostic and Statistical Manual Volume Three in 1984, the effects of disaster and war have been recognized for many years. For instance, the emotional consequences of disaster are described in the *Iliad*, and references to the terror induced by the attack of this hero are diverse. Ancient Greeks attributed epidemic illness to Apollo's wrath after the desecration of his temple.

The Mental Health Consequences of Military Operations and Disasters

Military and disaster psychiatry professionals have to understand the multitude of behavioral reactions to the spectrum of stressful events or stressors. While there is a good evidence base concerning risk factors for the development of post-incident mental health problems such as PTSD, professionals working in this area of psychiatry also have to understand how to distinguish normal reactions from those which indicate a need for professional services. This skill is often lacking in health care professionals who do not have expertise in this area. The precipitating stressor for PTSD involves a threat to the physical integrity of self or others leading to, often short lived, distress symptoms. Often those exposed to traumatic events experience helplessness, horror, or fear during the event itself although these reactions may well be absent in those who are prepared for the traumatic event or who have experience relevant to their actions during the event itself. For instance, war journalists may run toward the sound of a shot in a purposeful way in order to get their story or soldiers who are shot at may respond purposefully in accordance with their training.

However, even among trained individuals, there is a characteristic distress response which many but not all trauma-exposed individuals may experience. This response consists of symptoms that involve: (1) 'reliving' the original event (e.g., nightmares, distressing vivid recollections, or fear when exposed to events resembling the original trauma);

(2) cognitive or behavioral avoidance of events or situations that somehow resemble or symbolize the original trauma; (3) symptoms of increased vigilance, such as exaggerated startle, outbursts of anger, or other evidence of hyperarousal; and (4) negative changes in cognitions and/or mood, such as numbing of emotional feelings for others and highly negative appraisals of the future. If these symptoms of severe distress persist for over a month, then a diagnosis of PTSD may be appropriate if the symptoms are associated with significant functional impairment.

The symptoms of impending PTSD often occur within the first month after the trauma, and if severe may be termed acute stress disorder (ASD). PTSD itself is not diagnosed until at least a month after the trauma and there is a strong evidence base suggesting that the majority of cases of PTSD occur within the first 6 months after a traumatic event. In a minority of cases PTSD may be diagnosed for the first time after six or more months after the index event; this is termed delayed onset PTSD. There is considerable controversy persists regarding the diagnostic validity of delayed onset PTSD with some experts suggesting that delays in diagnosis result from delayed presentation rather than true delayed onset. In some cases, delay in onset may result from personnel who have experienced traumatic events remaining in a high state of alert and camaraderie after traumatic events. Such situations may be found among military personnel who experience traumatic events on a prolonged deployment and only find that they begin to think about their traumatic experiences once they have returned home or in communities who experience disaster but are initially highly supportive and functional as they strive to survive in the aftermath and/or as they reestablish a sense of normality. In these two examples it is quite understandable that proper processing of the traumatic event itself may be delayed, and thus so consequentially may the onset of the disorder.

Another important skill which military and disaster psychiatrists need to demonstrate is an understanding of disabling distress reactions that may occur in response to less significant trauma such as the unexpected loss of a key interpersonal relationship or loss of a job. Individuals, who experience significant but non-traumatic events, can present clinically within patterns of symptoms that are similar to those described by PTSD or ASD. However, the correct diagnosis in these cases is an adjustment disorder, which is characterized by maladaptive behavioral and/or emotional responses to a diverse array of stressors. Other psychological conditions may also follow exposure to intense stressors such as conversion disorder that may be diagnosed when someone develops unexplained symptoms or deficits affecting voluntary motor or sensory function (e.g., sudden paralysis of the 'trigger' finger in troops) without demonstrable neuroanatomical injury. Bereavement is a normal grief reaction after the death of someone who is valued or loved, may also occur in response to losses incurred during war or disaster. Other distress responses to war or disaster include anxiety and depressive syndromes, and antisocial behaviors that are not themselves related to frank mental disorders (such as acts of retributional violence or criminal behavior that may amount to war-related atrocities). Alterations in health-related behaviors (e.g., misuse of tobacco, drugs, or alcohol and risk-taking behaviors) may also develop after exposure to disaster or war. Taking a careful history including gaining a detailed understanding of pre-incident normal behaviors and attitudes as identifying relevant risk factors (e.g., history of childhood adversity and prior history of mental illness) as well as details of the traumatic event(s) and post-event reactions will allow military and disaster psychiatrists to decide upon the correct diagnostic label and treatment plan.

Battle Fatigue and Combat Stress

The terms 'battle fatigue' or 'combat stress' are broad and encompass a variety of responses to operational stressors but are not specific diagnostic constellation of symptoms such as major depressive disorder or PTSD. A wide range of physical and emotional symptoms and signs can occur among individuals with either condition including physical symptoms gastrointestinal distress, tremulousness, anxiety, perceptual disturbance, a sense of unreality, and a dazed look (i.e., 'thousand-yard stare'). Battle fatigue may be used to describe combatants who have exhausted physiological and psychosocial coping mechanisms with the intense combat experience whereas combat stress may be used to describe a more classic ASD reaction in the aftermath of particularly intense periods of fighting. It is noteworthy that minor injuries, infections, starvation, heat exhaustion, and cold injuries may decrease the coping resources of a combatant and predispose them to develop formal mental health difficulties.

Medically Unexplained Physical Symptoms

War historians have observed that medically unexplained physical symptoms (MUPS) are common sequelae of combat since at least the US Civil War. Syndromes such as 'soldier's heart' and illnesses characterized by physical symptoms attributed (by sufferers) to war-related exposure to Agent Orange or the pesticides and medical countermeasures as in the case of Gulf War syndrome are examples. Contentious debates between scientists, clinicians, veterans and their advocates, and journalists persist around putative etiology. Some argue that the consistent appearance of these syndromes after war speaks to the likelihood that psychosocial factors contribute to their etiology and importantly the particular role of speculation (by the media and politicians) in the absence of facts to rebut hearsay (Tarn et al., 2008).

Other Psychiatric Illnesses

While not confined to war or disasters, depression, anxiety disorders, and personality changes have all been associated with exposure to trauma. These psychiatric disorders may be accompanied by somatic complaints and may be related to either a traumatic event itself or the associated consequences (e.g., loss of lifestyle or of loves ones).

Risk and Protective Factors

Broadly speaking risk factors for the development of PTSD and other mental health disorders after traumatic incidents can be

divided into pre-incident factors, the nature of the incident itself, and factors relating to the post-event environment. The most influential are the post-incident factors as described in the following paragraphs (Brewin et al., 2000). Pre-incident factors include gender (women being diagnosed with PTSD more frequently than men), low educational status, childhood adversity, prior history of mental health problems, and/or socioeconomic disadvantage. There are many potential explanations for the existence of these risk factors including psychosocial factors, coping styles, cultural factors, and neurobiological explanations. It is also notable that individuals who have successfully negotiated past traumatic experiences may be resilient (sometimes described as 'hardened') in similar future situations. However, if past traumatic events resulted in PTSD, or other psychiatric distress syndromes, subsequent traumatic exposures may make future episodes of these disorders more likely.

Factors related to the incident itself include number and frequency of traumatic events, the nature of the event(s) (e.g., possible use of torture), moral challenges faced (did the person survive because others perished), and the physical/practical consequences of the event (e.g., physical injuries and loss of status, possessions, or loved ones).

The most influential factors in terms of longer-term post-incident mental health are the post-incident ones. Specifically, there is a wealth of good evidence that (1) having access to good social support (provided by people that the individual trusts and who honestly care for them) and (2) experiencing a low (but not no) pressure environment during recovery are the strongest determinants of good post-incident mental health. The understanding of these two factors and their effect on mental health are critical to influencing post-combat, or post-disaster mental health, and mental health care professionals who mistakenly intervene professionally without taking account of these two factors may inadvertently cause harm. There is considerable evidence that being exposed to post-incident mental health counseling (often termed 'debriefing') is, in the main, associated with no long-term benefit, but in some cases leads to a poorer outcome than not being 'psychologically debriefed' at all.

The protective nature of social cohesion is often most evident in defined groups such as the military or emergency services where strong camaraderie and leadership are commonplace. Both are powerfully protective in terms of post-event mental health status. Within military units, any mental health intervention has to take account of group dynamics and to a less extent the same is true for any population affected by disasters. For instance in the aftermath of a train crash, provision of treatment for someone who has developed PTSD without addressing the role they played during the event is unlikely to be successful. Within military units cohesion and leadership is often forged during preparatory training regimes and cemented during combat itself. The same is true for emergency responders during the aftermath of any traumatic event.

Similarly, although possibly more fragile bonds may form within previously non-coherent communities during and after disasters. After disasters the impact of statutory agencies in fostering a sense of security and safety, and preventing further exposure to stressors is critical. Symptoms in civilian victims of war or in the aftermath of disaster may be mitigated or exacerbated by perceptions of community leadership's preparedness for disaster, response to crisis, recognition of 'heroes,' and provision of medical, financial, or emotional assistance both immediately after crisis, and over time. Often a range of NGOs (e.g., the Red Cross or Red Crescent) may also provide input such as attending to basic human needs such as food, clothing, and shelter thereby reducing both the psychological and the physiological effects of the event. However, poorly coordinated post-disaster responses, can lead to confusion and anger in disaster affected communities with consequential effects on their mental health.

Management and Care Delivery

Often disasters or military conflicts shatter the expectation of a world as a just and safe place. Ideally primary preventative measures such as providing professionals with the right training, including importantly training managers/leaders about the impact of their behaviors on the mental health of team members will be in place before an incident occurs. Additionally most organizations that operate in high-risk situations will have selected their employees carefully, although it is notable that formal pre-employment or pre-deployment mental health screening has not been shown to be effective.

Once an incident has occurred interventions vary with the stage of the disaster. Initially, establishing a safe environment and managing life-threatening injury and disease possibilities, such as those resulting from infection or absence of potable water, can be the most important psychiatric interventions. Subsequently, identifying higher-risk populations such as disaster workers, firefighters, police, persons at impact zones, and children can focus intervention strategies. Post-incident mental health screening, a secondary prevention measure, may be effective in some populations (e.g., people who appear to be in difficulty after disasters or who consult a health care professional asking for assistance), but has not been shown to be effective in military populations probably because of concerns of personnel about the consequences of scoring positive in terms of their future career and the way they are viewed by peers and bosses.

Community outreach programs may also be important since disaster victims rarely seek mental health care. The physically injured are also at great risk for psychiatric disturbance. Educating medical and community groups about normal responses to traumatic events as well as when mental health referral is indicated as an important part of outreach programs. Providing information for families and work colleagues may also be important keeping in mind that the aim is to encourage them to provide good support without causing them to become unduly worried.

Military Mental Health Care

Military forces generally have in-house mental health provision that aims to provide both preventative intervention before operational deployments and evidence-based care for individuals who develop formal mental health disorders.

However, the primary aim of most military mental health care provision is to keep personnel psychologically fit, or return them to psychological fitness, so they can deploy to high-threat environments including combat and peacekeeping missions. Military mental health care provision may take place in home-base locations or in a deployed environment, although there is scant evidence about the effectiveness of treatment delivered in such conditions. Military health care professionals have to decide if personnel are ready for deployment where they may be required to protect colleagues or carry out other safety critical tasks. If deployed when not fully fit, poor concentration or impaired judgment, both characteristics of people who suffer with mental health problems, can lead to serious consequences for the individual and their colleagues.

Organizational Management of Traumatic Stress

Military forces, and other disaster responders, have a duty to provide appropriate care and support to their staff. In general the mental health of trauma-exposed personnel is more a function of good organizational preparation and camaraderie/leadership than the availability, or not, of mental health professionals. Organizational preparedness can include training for employees and managers to foster group cohesion (e.g., peer support training such as Trauma Risk Management (TRiM) developed in the UK (Greenberg et al., 2010)) or a variety of resilience training packages some of which (e.g., mindfulness-based approaches) have shown promise although well-conducted randomized controlled trials of these training packages is lacking. There have been various efforts to routinely screen troops after deployment in order to advise those with possible mental health disorders to seek help, but to date there is no evidence that these, costly processes, have been effective in spite of their widespread use (Milliken et al., 2007).

It is also noteworthy that many organizations who have a reputation for working in high threat locations have also been described as having a 'stiff upper-lip,' a term that infers that individuals within these organizations are reluctant to either acknowledge suffering from mental health problem or in seeking help for them. Research has however shown that in reality, a reluctance to seek help is common within all elements of society and not restricted to specific trades or groupings. However, help seeking is likely to be strongly influenced by the attitudes of the families of those affected by traumatic events and thus mental health professionals should take account of family views when formulating a management plan.

Possible Technological Advances

The modern battlefield is both rather similar and rather different to those of old. While troops are still, often, required to live in austere conditions and contend with threats to their health, and indeed live on occasion, more recent conflicts have been marked by the development of better communication with home than ever before. While there be many putative benefits of easy access to support from friends and family located far away, improvements in communication exposes deployed troops home stressors in, or nearly in, 'real time' that presents specific psychological difficulties. For instance, trying to talk to a child, who is missing their father, while he is being subjected to incoming mortar rounds can be challenging to say the least. However, disasters also may interrupt communications leading to distress. For instance, research carried out after the London bombings of 2005 revealed that distress was significantly more likely if respondents had been unable to contact loved ones around the time of the bombings in order to be able to verify their safety (Rubin et al., 2005).

Future wars will see troops having to deal with increasing technological advances in hardware such as the use of advanced sensors, weapons, and battlefield communication systems that require greater degrees of cognitive engagement than has been the case previously. Furthermore, the evolution of highly mobile units on widely disbursed battlefields will decrease the opportunity for exchanging rested troops from the rear area for those exhausted by frontline combat. Provision of brief respite for exhausted troops – a hallmark of management of battle fatigue – may become impossible as each individual may be performing a critical specialized task. Advanced technology will have similar implications for those responding to human-made disasters such as terrorist attacks especially as terrorists gain increased access to so-called weapons of mass destruction (chemical and biological agents). Clarifying the roles of military and civilian responders in terms of triage, treatment, consultation, and education in any joint response to crisis is another challenge for military and disaster psychiatrists.

Conclusions

Becoming involved with conflicts, including conflicts, or natural and human-made disasters can lead to deterioration in an individual's state of mental health. Much of the effect come from the result of disruption of individual's usual social ties and the pressures they have to contend with as they try to reestablish a sense of equilibrium post trauma. Whatever the cause, disasters and military operations leave in their wake populations experiencing psychological disturbances that have been well described by social scientists, civil leaders, physicians, and other care providers throughout the ages. Most people will recover from these difficulties without the need for formal interventions; however, a small proportion will require, or at least benefit from, evidence-based care. In most cases, however, those who do go on to develop mental health problems will either not recognize they are unwell or will be reluctant to seek help if they do.

The consequences of exposure to disaster and war may take the form of psychological disorders such as PTSD or may manifest as various (and sometimes more subtle) forms of behavioral change, anxiety, or depression. Symptoms may present at different times during and after traumatic exposure although the majority of post-event reactions come on soon after the event itself. Many factors complicate the evaluation and treatment of mental health disorders in the aftermath of war or disaster including resources being overwhelmed, life-

threatening physical illnesses or injuries requiring immediate treatment, and that psychological casualties are often reluctant to seek assistance.

In spite of the difficulties that military and disaster psychiatrists face, considerable progress has been made over recent years. We know that improving social bonds, providing psychological and physical safety, and adopting a watchful waiting approach are all likely to mitigate the effects of exposure to traumatic events. Furthermore, there is a range of evidence-based treatment approaches that are primarily based on the provision of focused, time-limited psychotherapies that can help individuals who develop mental health disorders after war or disaster affect a successful recovery. The value of multidisciplinary preparation and training for disaster management and the need for post-incident welfare and support, rather than counseling or therapy-based, outreach programs have also been demonstrated. Future work will hopefully identify how to bolster individual and group resilience and identify novel, or more rapidly delivered, therapeutic techniques, to improve recovery of those who become formally ill. Given that wars and disasters are likely to be a feature of our societies for many years ahead, military and disaster mental health care delivery will need to remain evidence based but flexibly delivered to provide the highest standard of prevention, evaluation, and care for individuals and groups devastated by war or disaster.

Abstract

Military geography aims to understand how military activities, organizations, institutions, and effects are geographically constituted and expressed. Military geography is broad in scope, and includes analyses of military land use, including and beyond battlefields and the environmental impacts of military activities; explorations of representations and interpretations of military landscapes; investigations of the economic and social relations effected by military capabilities; and the life worlds of military personnel. Future areas for military geographies research include the ways in which the changing nature of warfare produces new geographies of war, and the ways in which militarism as a social process continually reworks its spatialities.

Military geography can be defined in contemporary social sciences as the geographical constitution and expression of militarism, military activities, and militarization. Because these processes are multiple, with a huge variety of effects and manifestations, it is often more appropriate to talk of a plurality of military geographies. Unifying this field is an attentiveness to the ways in which places, spaces, environments, and landscapes are shaped by, and in turn have an effect upon, military capacities and military power.

This definition of military geography, dominant in the contemporary period, can be contrasted with an older definition of military geography as the application of geographical tools and techniques to military problems (Palka and Galgano, 2000). This more functional definition, that emerged with the discipline of geography itself, understands geographical scholarship in terms of its utility for the application of military power. More critical approaches toward military geography see the role of scholarship, rather, as understanding the effects of military capabilities and understandings, enabling a more sustained examination of how military activities and militarism operate as geographical processes, and how in turn geography shapes the military.

History of Military Geography

The history of the discipline of geography since the early nineteenth century shows geography's intimate connection to the pursuit of military power, control, and domination. With the development of colonial and later imperial ambitions among European powers, particularly Britain, and with the expansion of the territorial ambitions of the United States, we see the emergence of attempts by nation-states not only expand economic influence overseas, but also to undertake such ambitions through the use of military force. Geographical knowledge, of terrain, climate, biogeography, population, and settlement patterns, was an indispensable prerequisite for colonial and imperial expansion. In the United Kingdom, this is evident in the close association between military institutions and personnel and the establishment of the Royal Geographical Society. In the United States, this is evident in the establishment of military geography on the syllabus for trainee officer cadets at the US military academy at West Point. The understanding of military geography as assistive to military activities and ambitions stems from this period.

During the first half of the twentieth century, and specifically during the World Wars I and II, the labor power and skills of geographers were conscripted for the war efforts of the key protagonists in both conflicts. Recent research has established the centrality of the contribution of geographers and geographical knowledge to, for example, intelligence and information work, cartography, and surveying. Geography, conceived in this period as essentially descriptive of physical topography, environment, and patterns of human settlement and culture, was essential to the war effort specifically because the pursuit of strategic military objectives such as invasion and counterinvasion required, during both planning and execution, thorough knowledge of terrain, and a good understanding of local populations. We see the continuity of the idea of geography as a discipline of utility to the pursuit of military goals.

In the postwar period, three trends are evident, and are foundational to our understanding of what military geography might be in the present. First, we see the continuity of engagement between geography as a discipline informing military strategies and planning. This is evident, for example, in the adoption of emergent ideas about settlement distribution and spatiality in geographical science to urban planning anticipatory of the possible effects of nuclear annihilation during the Cold War. Urban morphologies at this time reflect ideas about the capacities for the maintenance of the nation-state under nuclear attack, particularly ideas about settlement dispersal (Farish, 2003). Second, more broadly across the social sciences and of particularly utility to geography, what has been termed the 'quantitative revolution' – the emergence of sophisticated techniques for statistical analysis of numeric data and the adoption of these techniques as a core element of geographical analysis and explanation – has shaped the nature of geographical inquiry. The symbiosis between the development of quantitative analysis and geographical information systems, and the demands of military strategists for techniques to model and thus plan and predict the effects of military activities, shows continuity (evident to the present) in the use of geographical techniques for the solution of military planning problems. Third, from the late 1960s onwards, the critiques

of patterns of power, domination, and control evident in advanced capitalist economies, by geographers energized by the ideas originating in Marxist thought, emerge as a radical geographical approach to understanding the spatialities of social life. Although there are indications across the later twentieth century of the recognition of the significance of military power as part of a wider analysis of geographies shaped by state power in conjunction with the demands of capital, the attention of radical geography to military forces and military activities as a focus for explicit scrutiny emerged only slowly.

However, toward the end of the twentieth century and into the present, contemporary geographical scholarship has turned to military topics as a more central focus of study. Political geography, reinvigorated by the ideas of those writing a critical geopolitics to explore the representational and discursive portrayals of states and strategists, has engaged more directly with the organization, execution, and effects of military power (Dalby, 2010). Military forces, activities, and effects themselves have invited explicit focus in terms of their transformational potential for shaping geographies (Woodward, 2004; Graham, 2010). Long-running armed conflicts in Central Africa and Southeast Asia, and the wars in Iraq and Afghanistan in the first decade of the twenty-first century, have both prompted a wealth of analytic investigation by geographers whose critical and condemnatory overview of the deployment of military power and its catastrophic effects are prompting a renewed consideration of just why geography as an academic discipline needs to be attentive to militarism, military activities, and war.

The Scope of Contemporary Military Geography

The scope of contemporary military geography is broad in terms of topics for investigation and analytic approaches to those topics. It is also notable that those working within military geography draw extensively on the conceptual and theoretical insights of other areas within the subdiscipline, such as political, economic, social, and cultural geography, and more widely across the social sciences. While military geography has at its heart a concern with the geographical constitution and expression of military activities and effects, it is in its contemporary form clearly allied conceptually and politically to a broader movement within sociology, anthropology, women's studies, political science, and international relations which seeks to establish not only the patterns and consequences of military power, but also – and crucially – the conditions which make the deployment of military force possible in the first instance. Thus we can see a divergence between more traditional military studies which see military phenomena as a given, functional category, and a more critical military studies approach which sees military processes and practices as the outcome of social life and political contestation.

Terrain, Tactics, and Land Use

A core component of contemporary military geography is the examination of the geographies of military activities in terms of the interrelationship between terrain and military tactics, and in terms of wider questions of territorial control and land use in nonconflict and domestic as well as conflict and postconflict settings. The analysis of both terrain, in terms of geomorphological conditions and effects, and of factors such as meteorological conditions pertaining in particular times and places and their influence on specific military encounters, has been a source of fascination and interest to many seeking to explore historical campaigns and battles (Doyle and Bennett, 2002). Technological developments in surveying equipment and mapping, including LiDAR and other remote sensing techniques have enabled geographers to track and trace the evidence for past incidents across lost battlefields, and to map in fine detail the course of specific tactical encounters between military forces. An emergent subdiscipline of combat archaeology draws on geographical and archaeological exploratory techniques and environmental reconstruction methods to establish in more detail local biogeographical conditions in sites of both conflict and of longer-standing military occupation. In terms of land use and military presence, and reflecting a long-standing interest among geographers not just in patterns of human activities but, crucially, conceptual explanations for the spatial constitution and expression of military activities, interests range from the exploration of the political economies of military basing, through to the representation and reimagination of regions and large areas of territory by military planners and strategists and the wider politics of such constructions (Farish, 2010). Military geography is also exploring the spatialities of military airspaces (Williams, 2011).

Environmental Impacts of Military Activities

Military activities, across a range from the pursuit of armed combat through to domestic training and basing activities, are enormously detrimental to the natural environment. Military geography, as a subdiscipline interested in the totality of military activities and the range of potential geographical effects, therefore seeks to account for the environmental activities, and to explore in addition the strategies deployed by governments and their military forces in explaining and accounting for such impacts. Military activities impact on the natural environment in the first instance through the sheer scale of consumption of natural resources, required for the execution of military power; resources include fuels, precious metals, ferrous metals, and hydrocarbons for the manufacture of weapons systems including munitions, and the provision of energy for their deployment. The conduct of armed conflict is damaging to environments through the physical modification and destruction of habitats and local ecologies; through the pollution effects of chemical, biological, and nuclear contaminants released through military operations; and through the residue of ferrous, heavy metal, and chemical pollution on sites of military engagement. Nonconflict activities, which are essential for the preparation of armed forces to the readiness states required by their national governments, are similarly destructive through the modifications imposed by basing, logistics, communications, and training infrastructures (including the requirement for training areas by land forces), by the erosion and soil compaction effects of tracked vehicles, by pollution from the leakage of fuels and lubricants, by the litter of used practice munitions, by noise effects of military training, and by human interference and presence in specific environments. Of concern to military geography too are the

rationalizations produced to manage and explain such effects. For example, former military sites affected by unmanageable and unremediable contamination may be declared as sacrificed with future uses impossible due to contamination (Havlick, 2011). Of interest too are the policy mechanisms established for the remediation of former military lands with levels of contamination low enough to allow land reuse following restorative work. Interest in these policy mechanisms extends to the discursive and representational practices deployed by military forces and state interests in explaining to a wider public both the effects of military activities on the environment, and the rationale for allowing negative impacts where it is thought that national military interests prevail.

Representing and Reading Military Landscapes

In keeping with a long-standing core interest in human geography in the identification, reading and engagements with landscape, military geography seeks to explore how military landscapes work (Woodward, 2014). Approaches include considering how military forces themselves read landscapes for military purposes, from the scale of the individual and personal with the activities of personnel on the ground assessing terrain for tactical reasons, through to the large-scale surveying of landscapes for more strategic military maneuvers. Practices of landscape interpretation owe much to geographical skills in reading terrain and establishing viewpoints, and here again we see the coevolution of military techniques alongside those of geography as a discipline. This is evident, for example, in the development of cartographic practices and aerial surveillance techniques during and after the World Wars I and II, and in more contemporary examples where military personnel seek new methods for thinking through the spatialities of urban landscapes for military purposes, including the control and domination of resident insurgent populations. Military landscapes and landscapes of militarism also include the settlements and infrastructures associated with military basing, both in domestic and overseas contexts (Lutz, 2001). Of particular interest are the transposition and installation of urban morphologies adapted for military requirements by US forces in their domestic setting, to overseas garrison towns and territories under military control (Gillem, 2007). Landscape interpretation is also a representational strategy, and as public organizations funded by national governments, many national military forces are increasingly concerned to provide a narrative about the appropriate reading of landscapes as a means of legitimating a military presence. So, for example, training areas which might otherwise be thought of in terms of their landscape qualities come to be portrayed not only as constitutive of the value of a nation's territory, but as significantly military as part of that value.

Reading and engaging with military landscapes is also a civilian practice, and nonmilitary understandings and interpretations of military landscapes have proven a fruitful area for military geographical inquiry. One of the most immediately obvious and dramatic types of military landscape, prompting a wealth of inquiry, is memorial landscapes around past military activities. Studies of, for example, the landscape effects of memorials and cemeteries associated with the World War I in northern France and Belgium, explore the intersections between ideas of national identity and national sacrifice with more individual and personal needs for mourning and recognition of loss. There is also a substantial interest in the geographies of postmilitary landscapes. Across European and North American contexts, for example, successive rounds of investment in military capabilities, superseded at regular intervals through changing geopolitical power configurations, technological and developments in weapons and communications systems, and national defense strategies, have generated landscapes of ruin and redundancy. These are of interest not just for their exposure to civilian gaze in the aftermath of (usually fairly secretive) military use, but also for what they tell us about social priorities for the care and protection, or redundancy and destruction, of symbols of past military priorities and histories into the future. Visual representations of military landscapes, including postmilitary landscapes as well as responses to conflict and its effects, are of increasing interest within military geography because of the insights which artistic responses generate as part of a wider conversation about militarism and its spatial and landscape constitution and expression (Ingram, 2011). Military geography is also concerned with the phenomenological and post-phenomenological experience of being in landscape, following conceptual developments in wider landscape studies, and so the significance of the personnel, embodied, experiential encounter with militarized space is also of relevance here (Sidaway, 2009).

The Geographies of the Military Economy

Military forces and their activities are recognized as significant economic actors, and drawing on the insights of economic geography, military geography seeks to understand how military effects on economies and labor markets are played out at a range of different scales, and how they intersect with other economic processes. The changing nature of the defense industry, particularly the consolidation of manufacturing and research and development capabilities, has had profound local and regional effects in terms of concentrations, consolidation, and decommissioning of defense industry activities with knock-on effects for labor markets. There are also patterns of global economic change brought about by the transnational nature of an industry increasingly footloose from national and supranational political control. Military economic geography is interested in patterns of basing and deployment of personnel, and in patterns of consumption and expenditure consolidated within particular localities domestically and overseas as they follow personnel deployments. There are also economies associated with the provisioning of military forces, including questions about the embeddededness or otherwise of forces within local economies as a consequence of military supply chains for basic commodities.

Reflecting a trend underway from the end of the Cold War,-and gathering pace under neoliberal regimes of governance and economic management by nation-states, the privatization and outsourcing of military activities is an increasingly significant issue for military forces, and correspondingly for military geography. This has led to some arguing for a reconceptualization of the geopolitical as the geoeconomic social, reflecting the potential scale (according to proponents of

this argument) of the shift in the deployment of subcontractors for an increasing array of military functions (Cowen and Smith, 2009). The range of outsourced and subcontracted activities includes the use of personnel for both officially recognized personal protection (and there are indications of its use for more clandestine operations where visible deployment of regular armed forces would be politically problematic), the subcontracting of a range of logistics and supplies functions, including catering, health, welfare, and administrative services, the contracting-out of training functions involving the providers of weapons and transportation systems, and the outsourcing of land management and training area maintenance functions in some cases. It should be emphasized that these are all tasks which 40 years ago would have been conducted in-house by regular armed forces personnel. The consequences of this shift toward privatization and outsourcing are various. Benefits argued for by proponents of this shift, and recognized even by some critics, include the delegation of activities best undertaken by those with the requisite skills and training but who do not require a military role to undertake the task. More problematic are questions about accountability and viability of the subcontracting of activities around the deployment of armed violence beyond the state's nominated and legitimized representatives (Gallaher, 2012). There is clearly a geography to this pattern of subcontracting, and military geography is increasingly alert to the complex political economy of privatization of military forces, and the spatialities and scalar effects of modes of neoliberal management in the organization of military activities.

Military Personnel

Reflecting the engagement of human geography with matters of social and individual identity, subjectivity, and embodiment, and with the exploration of issues such as class, ethnicity, gender, and sexuality as organizing features of social relations, military geography is similarly interested in military personnel as people, and more collectively. Military geography has explored the social construction of military identities with reference to the spatialities inherent in that process through, for example, explorations of the intersections between military masculinities and space, with reference to different spatial and temporal contexts and in locations as diverse as the battlefield, the parade ground, the training area, and the barracks. The use of ideas about gender, gender roles and gender relations within military units, and specifically the spatialities through which these relationships are constituted and expressed informs broader debates about women's military participation. The effects of hegemonic ideas about military masculinities and their enactment through social space similarly inform broader social scientific debates on gender identities. Geography, as a discipline alert to the significance of the visual in representational strategies, seeks to explore such issues with reference to the imagery used to consolidate dominant ideas about gendered identities within military forces. The construction and articulation of representations of the figure of the soldier, and the variety in these across different national contexts, also figures in explorations focused on the broader social understanding of the figure of the military operative and his or her place in the world, as part of wider explorations of civil-military relations.

Most military geography is concerned with the institutions and personnel formed and deployed with the authority of the nation-state for the exercise of potentially lethal yet state-sanctioned violence. However, not all militarized violence is conducted by state military forces, and military geography is alert too to paramilitary, insurgent and revolutionary militarisms which are so often emergent in response to state military violence. Examining nonstate military actors raises particularly interesting questions for military geography, precisely because of the contingencies of nonstate funding in shaping military objectives and activities, the deployment of nonstate military personnel, and the specific social position of the nonstate operative, revolutionary, paramilitary, or insurgent.

Future Directions in Military Geography

Military geography is essentially a set of engagements with a range of practices which reflect often very rapid temporal and spatial change. Developments in nation-states' strategic interests and internationally collaborative ambitions, combined with evolutions in military capabilities and policies, and shifting geopolitical realities at a range of scales, means that the subdiscipline of military geography is marked by its dynamism. Indications of potential future avenues of exploration for military geographies reflect such changes.

The first of these concerns the changing nature of warfare and of ways of engaging with armed conflict by state and nonstate actors. Although (as already discussed) there are indications that much of this agenda is starting to be addressed, it is necessary to emphasize the significance of current changes in the nature of war for future military geographical inquiry. Key issues here include the increasing urbanization of warfare as a deliberate, strategic choice by many national military forces, and the consequences of this for the use of geographical techniques of surveying, particularly regarding their use for purposes far removed from the intentions of those responsible for their development. The noted twentieth-century shift to war as a civilian issue, rather than a purely military affair, continues apace, and armed conflict is increasingly utterly all-encompassing for those caught up in it directly and along its margins. The use of preemptive force has tremendous consequences for civilian populations. We can also note the growing interest in environmental security and resource wars as foundational to twenty-first century conflicts.

The second area for future research which is highly relevant to military geography speaks to cultural geography's longstanding interest in the construction, articulation, and reproduction of meaning with reference to space and social life. Militarism, often understood as the extension of military priorities into civilian life, is among other things a cultural practice, and military geography is well placed, with its focus on the spatial constitution and expression of military phenomena, to make critical interventions as analysts grapple with the circulation of ideas about military power and priorities in civilian sociocultural life.

Abstract

Military history is the history of wars, and of armed forces in peace as well as in war. Its separation from history, more broadly defined, arises from its didactic purpose. Its origins therefore lie with the development of professional armies. The growth of history as a university subject from the late nineteenth century did mean that academics as well as soldiers studied the history of war, but its institutional foundations were shallow. Moreover, soldiers rather than academics wrote the official histories of World War I. The situation only changed with the adoption of broader definitions for the official histories of World War II. The world wars themselves showed the absurdity of approaching the study of modern history without taking military history into account. Since the 1960s academic military history has thrived.

Military history is the history of wars, and of armed forces in peace as well as in war. Its separation from history, more broadly defined, arises from its didactic purpose. Its origins therefore lie with the development of professional armies. The growth of history as a university subject from the late nineteenth century did mean that academics as well as soldiers studied the history of war, but its institutional foundations were shallow. Moreover, soldiers rather than academics wrote the official histories of World War I. The situation only changed with the adoption of broader definitions for the official histories of World War II. The world wars themselves showed the absurdity of approaching the study of modern history without taking military history into account. Since the 1960s academic military history has thrived on the back of two influences. The first, 'the new military history,' is largely American in origin and stresses the subject as a component of 'total history.' The second, strategic studies, relates past to present.

The easy definition of military history is that it is the history of wars. And yet this definition is highly imprecise. Wars have social, economic, and political dimensions that have been analyzed more by the historians of those subdisciplines than by military historians. That is not to say that there are no important links to be made between military history and other historical subdisciplines, nor is it to deny that the good military historian endeavors to make those connections. But in terms of their subject matter military historians have been concerned primarily with the histories of armed forces, not only in war but also in peace. Military history has therefore been more comfortable with wars fought by armies and navies than with wars fought between warrior societies, or before soldiering became a distinct profession.

The Emergence of Military History as a Separate Subdiscipline

Thucydides wrote the history of a war, and – like some other ancient historians – himself saw service. But it would not be reasonable to call him a military historian. It required the growth of professional armies and the concomitant influence of the Enlightenment for the ancient historians who wrote about conflict to be treated as military historians rather than as historians *tout court*.

The Influence of Professional Armies

In the 1590s, Maurice of Nassau developed systems of infantry drill and of military organization that standardized tactics and were emulated throughout Europe. This was the basis for what in 1956 Michael Roberts called the 'military revolution' – a clutch of changes that occurred in warfare between 1560 and 1660. The Thirty Years' War in Central Europe, the Fronde in France, and the British civil wars served to disseminate the principles of the 'military revolution,' which found their seventeenth century apogee in the Swedish army of Gustavus Adolphus. Subsequent historians have elongated the chronology of the 'military revolution.' Geoffrey Parker sees its origins as before 1560, in the growth of a new style of artillery-resistant fortification, the *trace italienne*. Others have highlighted developments after 1660, calling the growth in army size under Louis XIV and the maintenance of armies in peace as well as in war a 'second military revolution' (Rogers, 1995). The essential points are that over the course of the period 1500–1800, armies as we now recognize them evolved, and that those armies then became the basis of imitation within Europe and the foundation of empire outside it.

During the course of the eighteenth century the aristocracies of Europe, now subordinated to the crown and state, made soldiering their vocation. Military academies were established, not only for the training of the scientific arms – the artillery and engineers – but also for the cavalry and infantry. The combination of institutional continuity and professionalization promoted the study of war. The writings of the ancients were supplemented by the effusions of eighteenth century practitioners – including Maurice de Saxe, Henry Lloyd, and G.F. von Tempelhoff – who combined theoretical musings with a distillation of their own experiences. Military history had didactic rather than scholarly origins.

The Enlightenment

The study of past wars as a means of improving present practice was, at one level, entirely consistent with the precepts of the Enlightenment. War, like any other human activity, could be seen as a science, based on unchanging principles, themselves derived from actual experience. The wars of Frederick the Great,

a child of the Enlightenment and a major writer on war, served to promote these connections. Over 70 works of military theory were published in the seventeenth century, but more than twice that in the eighteenth century, in particular, over 100 during the period 1756–89 (Gat, 1989).

Napoleon was both a product of this tradition and its most distinguished advocate. William Napier, an unstinting admirer of the emperor, established British military history with his account of the Peninsular War. Although Napier eschewed theory, his history was influenced by the most important military theorist of the nineteenth century, A.H. Jomini. Jomini's *Traité des grandes opérations militaires* (first two volumes, 1804) became a five-volume history of the wars of Frederick the Great and Napoleon, with a resumé of the general principles of war tacked on as a conclusion. His *Précis de l'art de la guerre* (1838), which shaped the syllabuses of military academies into the twentieth century, put the theory first but still relied on history to make its points (Shy, 1986; Alger, 1982).

Carl von Clausewitz was critical of Jomini, but like him, wrote far more history than theory. Moreover, his principal work, the unfinished and posthumously published *Vom Kriege* (1832), relies on history for its evidential base. Clausewitz stressed his anxiety to break with the nostrums of earlier military writers, but he is no different from them in his readiness to cull military history for normative purposes.

At one level, therefore, the influence of the Enlightenment on the development of military history operated internally – it helped define how and by whom war was fought. But its consequences were also external to the subject. The phenomenon of war itself appalled the *philosophes* – not the least Frederick's friend, Voltaire. Their efforts to curb and moderate its effects, stoked by the memory of the Thirty Years' War and its terrors for the civilian population, took shape through international law. War became an activity clearly distinguished from peace, undertaken by specialists separated from civilian society but who, crucially, acted not on their own account but on behalf of the state. For the *philosophes*, war was not necessarily endemic in society. Those who built on the legacy of the Enlightenment, the liberals of Victorian Britain in particular, could see it as an activity that was not honorable but reprehensible, maintained by the aristocracy with the aim of sustaining their own hold on society, and replaceable by alternative forms of interstate competition, particularly trade.

Academic Neglect of Military History

The legacy of liberalism was a belief that military history was not a proper study for universities. As history gained a foothold in the curriculums of European higher education in the last third of the nineteenth century, war ought to have been central to its preoccupations. Indeed, at one level it was. Historians of the ancient or medieval worlds could not neglect war entirely, but they still preferred to focus on more humane developments, on 'progress' in law, religion, or the machinery of state. Equally, no nineteenth century scholar could neglect the impact on Europe of the Napoleonic Wars or the wars of German Unification – as Archibald Allison showed for the former, and Heinrich Friedjung for the latter. But they neglected the conduct of war itself: war was an aberration, inimical to the 'Whig' view of history. The advent of nuclear weapons in 1945, with their threat of a war so awful and so complete that war and peace became absolute terms rather than points on a scale of relative values, completed this marginalization. Diplomatic historians looked at why wars occurred, at how they were ended, and at efforts to avoid them thereafter, but the history of war itself was left to its practitioners.

This picture of academic neglect, still propagated but with much less reason in the twenty-first century, is overdrawn. There were major exceptions, even if it remains true that those exceptions prove the rule.

The founding father of academic military history, Hans Delbrück, served in the Franco-Prussian War and believed that universities should recognize military history. He planned to do his *Habilitation* on a military historical topic, but both Heinrich von Treitschke and Theodor von Mommsen, the leading historians in Berlin, opposed the idea. Delbrück persisted with his enthusiasm and in 1883 announced his intention to write a general history of war in its political context. Leopold von Ranke told him that the study of war was not appropriate to a university, and when Delbrück was appointed to a chair in 1895 (ironically as Treitschke's successor) it was in 'universal and world history.' In 1900, Delbrück published the first of the four volumes of his history of war. Mommsen told the author that he would not have time to read it (Bucholz, 1985; Deist, 1998).

Delbrück also alienated those to whom his work ought to have appealed. He argued that Frederick the Great had not sought decisive battle but had preferred to exhaust his enemies by maneuver. The German army's general staff was incensed. Its own studies of Frederick's campaigns were extensive, but their purposes were more didactic than scholarly. Institutionally, this loyalty to Frederick (rather than to Napoleon) as the founding father of modern war predisposed them to see him as the advocate of a strategy of 'annihilation' rather than of 'attrition' (Bucholz, 1985; Lange, 1995).

At one level, therefore, Delbrück was an isolated figure – virtually unique in the academic world of Wilhelmine Germany, and vilified by the one institution that thought deeply about the history of war. But he was not uninfluential. He had been tutor to the Kaiser, he was a Reichstag deputy, and he edited the *Preussische Jahrbücher*. He emerged from World War I a leading figure in Germany's public and intellectual life. As a role model his legacy spread in two directions. First, his interpretation of military history was essentially Clausewitzian; he studied war as a state activity, and as an agent for the implementation of strategy. Second, he treated war as a discrete phenomenon, possessing an integrity from the ancient world to the modern. Historical knowledge so defined was the basis for pronouncements on current strategic issues.

Delbrück's institutional legacy proved more short lived. Military history was established at the Friedrich Wilhelm University in Berlin after World War I. But the subject was usurped by the Nazis. For a long time after World War II there was no established chair of military history at any German university, with the exception of the post created for the Clausewitz scholar, Werner Hahlweg, at Münster in 1969. Only in the 1990s did the subject reassert itself in research terms, and a professorship was established at Potsdam.

In Britain, also, individual careers punctured the image of academic neglect. The Regius Professor of Modern History at Oxford between 1904 and 1925, Sir Charles Firth, was a historian of the English Civil War and of Cromwell's army. The same university's Chichele Professor of Modern History from 1905, Sir Charles Oman, wrote a massive and definitive history of the Peninsular War. In the same year Oxford created a lectureship in military history, strategy, and tactics, and in 1909 established the Chichele chair in the history of war. Thus in Britain, unlike Germany, the subject acquired an institutional focus. Two years later, Cambridge followed suit with the Vere Harmsworth chair of naval history. King's College London, whose professor of modern history, J.K. Laughton, had been involved in the formation of the Naval Records Society in 1893, formed a department of naval history in 1913 but failed to make an appointment (N.A.M. Rodger in Hattendorf, 1994).

In Germany, the effect of World War I was to institutionalize personal initiative; in Britain, its effect was to undermine the progress already made. Spenser Wilkinson, who had been appointed to the Oxford chair, had been a journalist, and – like Delbrück – had linked the study of military history to current policy issues. But, unlike Delbrück, Wilkinson did not join the public debate on the strategy of World War I. He turned to scholarly studies of the eighteenth century and, his eyesight failing, became a marginal figure. Until the appointment of Sir Michael Howard to the chair in 1977, his successors lacked academic punch (Ernest Swinton), were tarred with the brush of journalism (Cyril Falls), or were unproductive in publication terms (Norman Gibbs). The burden of actual teaching throughout this period fell on C.T. Alkinson, whose output was considerable, but who tended to antiquarianism as well as personal eccentricity. In Cambridge, the Harmsworth chair married naval and imperial history in 1932, to the eventual detriment of the former.

General Staffs and Official Histories

The failure of the universities in Britain to master military history was displayed by the allocation of responsibility for the official histories of World War I. The accounts of naval and military operations were both put in the hands of civilians – Sir Julian Corbett and Sir John Fortescue, respectively. Neither man held an academic post. Corbett was a lawyer by training, but his interest in contemporary maritime doctrine, as well as in naval history, qualified him admirably for the task. Fortescue was writing a *History of the British Army* in what proved ultimately to be 13 volumes, but he derived his principal income from his appointment as Royal Librarian. His enthusiasm for colorful accounts of Napoleonic battles produced a prose style and a conceptual approach unequal to the nature of modern war. He was replaced by a team of soldiers, headed by Sir James Edmonds.

Thus, the bulk of Britain's official history program ended up, by default, being run on lines not dissimilar to those of the other belligerents. In the wake of Prussia's victory in 1871, the major land powers had established or reestablished their general staffs, charged with planning in peacetime and operational direction in wartime. The staffs' study of history flowed from their responsibility for doctrine and training. During the period 1871 to 1914, massive military histories of continuing scholarly importance were published, either by the historical sections of the general staffs (the Germans devoted 19 volumes to the campaigns of Frederick the Great) or by individual officers with staff training. The conceptual basis of current understanding of Napoleonic warfare was established in this period, by French officers such as Jean Colin and Hubert Camon.

These were the bodies and individuals made responsible for the official histories of World War I: the Austro-Hungarian was in the hands of the Bundesministerium für Heereswesen and the Kriegsarchiv, the French in those of the Ministry of War, and the German in those of the Marinearchiv (for naval operations) and the Reichsarchiv (for land operations). Although the latter were nominally independent of the armed forces, in reality the personalities and the agenda showed the thread of continuity.

Thus, the biggest projects in military history ever undertaken were given to soldiers rather than scholars. Their justifications became didactic, and their focus tactical and operational rather than political or economic. Full accounts of campaigns were not matched by comparable analyses of economic mobilization or strategic direction.

After World War II, academics regained some of the ground they had lost, but the effects were partial. The British official history was conceived in much broader terms, and a division of labor between dons and soldiers established, the former being tasked with both the 'civil' and the 'strategic' series. In the USA the history of naval operations was entrusted to S.E. Morison, a Harvard professor. Elsewhere, however, military history narrowly defined, remained largely in the hands of the successors to the general staffs' historical sections. France has *services historiques* for each of its armed forces, and there are few historians of warfare in university posts. With distinguished exceptions, such as the medievalist Philippe Contamine and the modernist Guy Pedroncini, the study of war in French academic life has been dominated by its relationship to social history – either the social composition of armies (André Corvisier has been a pioneer here) or the impact of war on society itself (where Jean-Jacques Becker has been a leader). In Italy, although in the 1960s and 1970s Giorgio Rochat, Massimo Mazzetti, and others began to challenge the domination of the official histories, the armed services' grip on the subject has remained powerful. In Germany, the Militärgeschichtliche Forschungsamt was created in 1957 under the auspices of the Bundeswehr. It has, however, recruited civilian scholars as well as uniformed members, and its publications have maintained rigorous standards that defy the self-serving purposes of the didactic tradition to which it is nominally the heir. Its monumental history of Germany in World War II shows a willingness to confront its armed forces' recent past, which contrasts strongly with the pattern in Japan. Here, the rejection of a nation's militarist inheritance has also resulted in the atrophy of military history.

The Didactic Tradition

Governments and armed forces sponsored the writing of official history because they hoped to derive from it 'lessons' for

future application. But their labors produced accounts so voluminous and so long in production that the lessons were in danger of being lost or forgotten. Into this gap stepped others, preeminently but not only J.F.C. Fuller and Basil Liddell Hart in Britain, who unashamedly used military history as a prescriptive basis for the future. Like Delbrück, they ranged from the ancient world to the present, but unlike him, their focus was tactical rather than strategic. Even Fuller's and Liddell Hart's ostensibly historical works, whose popularity endures, retain a theoretical purpose.

The 'New' Military History

In the short term, therefore, the effect of the two world wars was the reappropriation of military history by the armed forces for purposes that were instructional rather than academic. But in the long term the all-embracing nature of both wars made the marginalization of military history within university circles unsustainable. Once the first half of the twentieth century entered the curriculum, war could no longer be left out.

The idea of total war was used to underpin the idea of total history. War became central, rather than peripheral, not only to the period 1914–45 but to every other period as well. Ancient and medieval history was particularly susceptible to this approach. But its success can best be measured by consideration of the eighteenth century. The 'didactic' tradition had seen this as the era of limited warfare, when armies maneuvered rather than sought battle, and wars were indecisive affairs conducted by professional armies cut off from civil society. Current scholarship sees eighteenth century warfare as involving a much larger cross section of society, and is far readier to apply the vocabulary of modern war to conflicts like the Seven Years' War and the American War of Independence. Their length and geographical extent are seen by some as prefigurings of world war.

The 'new military history,' a term coined in the USA in the 1960s, indicated that the history of war was not simply about 'great captains' and their conduct of operations (Paret, 1992). Military history embraced the study of armies in peacetime, and war's cultural, economic, and social effects; it had a responsibility to explore its links with other subdisciplines in history. The main directions in which the subject moved were toward 'war and society,' both narrowly and broadly defined. The narrow definition meant the analysis of an army's social composition, and also its effect on civil–military relations. The broader definition considered war's effects – economic and cultural – on civil society.

As a campaigning tool the 'new military history' proved remarkably successful, not the least in the USA. In 1954, only 37 of the 493 colleges and universities in the USA offered courses in military history. By 1989 164 of the 554 institutions taught military history, and more than 2% of all historians in America were military historians. This calculation excluded the officer training courses (the ROTC), which accounted for about 400 more military historians. In the mid-1970s in the USA about 100 doctoral theses a year embraced military history; 20 years later the figure had tripled (Don Higginbotham in Charters et al., 1992; Kennedy, 1989).

Military historians established their subject by redefining themselves in interdisciplinary terms: they explained why they were not military historians, or at least not in the traditional sense, but 'total' historians. Although its advocates continue to promulgate the 'new military history,' its point has been made – it is now not so 'new.' So well absorbed have its points become that academic military history is increasingly returning to a narrower definition of its roots. Warfare itself is now a subject fit for self-contained study, and academics working in the field publish in journals devoted exclusively to military history rather than to general history. The argument that war is part of total history no longer has to be made.

The Rediscovery of Clausewitz

One of the reasons why Delbrück was at odds with the general staff was that he and they were not comparing like with like. Delbrück's focus was on war as a political act, as the means to fulfill strategic objectives. The general staff saw war as a self-contained phenomenon. Since 1945, Gordon Craig, Gerhard Ritter, and, above all, Michael Howard and Peter Paret have operated within the Delbrückian interpretation. It is hard to underestimate the intellectual consequences in the anglophone world of Howard's and Paret's translation of Clausewitz's *Vom Kriege*, which appeared in 1976. It relieved Clausewitz of the incubus of obscurity and ambiguity, and it put the focus firmly on books 1 and 8 of *Vom Kriege* – those that deal with the relationship between war and politics: this was a primer for the vocabulary of nuclear deterrence as much as it was an insight into Napoleonic warfare.

Although Paret approached the task as a historian of ideas, Howard did so as a student of strategic studies. Through his revitalization of the war studies department of King's College London in the 1960s, Howard reforged the links between military history and current policy (Howard, 1983). His own subsequent distinction in both fields, at Oxford and then at Yale, ensured that, in the UK at least, the health of military history was tied in to the study of international relations. In the USA as well as in continental Europe the relationship between military history and strategic studies has been more antagonistic. The cynic would say that, deprived of the armed services' commitment to the study of the subject, evident especially in Germany and France, and lacking the financial resources of the history departments of American universities, British military history has had no option but to embrace a marriage of convenience.

There are therefore distinct national approaches to military history, reflections in large part of the institutional diversity of its roots. Comparative military history has barely begun. Moreover, the strengths and weaknesses of each national school can reflect the fact that this form of history above all is tied in to the nation-state, its formation, and its self-identity. German military history since 1945 has predictably been concerned with World War II to the detriment of earlier wars; the Soviet Union largely ignored Russian military history before 1917. But both these patterns are being broken down. And Britain, which according to this sort of logic ought to be leading the world in naval history, actually let the subject crumble in the 1970s and 1980s.

'Popular' Military History

The popularity of military history outside the confines of universities and staff colleges, at least within the UK and the USA, makes military history an obvious route by which to introduce the nonspecialist public to history more generally. Some of the writing, such as that of Henri Lachouque or Georges Blond in France, can come close to romantic nostalgia; the work of others, such as Paul Carell on the Wehrmacht in World War II, can seem striking for what it leaves out. But the best work in this genre – both German Werth and Alistair Horne on Verdun, for example – deserves, and has received, serious attention from scholars. In Britain, John Keegan and Antony Beevor have thrived on the back of military history's flowering in academic circles. Much of what they do is traditional. Keegan, like Liddell Hart, ranges across time and space; like Liddell Hart he also writes with the fluency and ease of a journalist; and, as with Liddell Hart, there is a didactic thrust. But the appeal is also in the narrative, as the staggering success of Beevor's *Stalingrad* (1998) displays. Keegan (1976) criticized historians of war who focused on its operational and tactical level but failed to explain the experience of combat itself. Beevor's book puts such precepts into practice. The academic world has also responded to Keegan's call. Research on war 'from below' not only has popular appeal but also interdisciplinary potential.

Military historians continue to complain that they are marginal figures in the academic world. In mainland Europe, that complaint has some substance, but becoming less year on year. And in the USA, where it is stated most vociferously, it is without serious foundation. However, its current strength derives in large part from its past battles to establish itself. Lacking a linear pedigree, military history is a hybrid whose resilience derives from the multiplicity of its approaches.

Military Sociology

Abstract

The field of military sociology is interdisciplinary and international. As the discipline developed, concepts were incorporated not only from other social sciences, but also from cultural shifts and political demands on the military.

From an initial focus on enlisted ground combat forces, dominated by U.S. sociologists during and following World War II, the military sociology agenda expanded to include professionalism, civil-military relations, changing military operations, families, veterans, and reservists in all branches of the armed forces and in many nations.

Introduction

During the development of Western sociology as a discipline in the late eighteenth and nineteenth centuries, early European sociologists saw war and conflict as important social processes on a continent repeatedly affected by war. In spite of the attention European sociologists paid to military forces as the organizations that waged those wars, the continental sociology transported to the United States of America reflected the more pacific theorists and theories, and disregarded an awareness of the military (Malešević, 2010). Thus, while Max Weber's theory of bureaucratic organization came to be widely taught in American sociology and political science departments, organizational psychology programs, and colleges of business and management, the fact that Weber's prototype had been the Prussian army was generally overlooked; and while Durkheim's theory of suicide became a staple of American sociology, the category of heroic suicide – for example throwing oneself on an explosive device to protect one's comrades – as a form of altruistic suicide, was virtually never mentioned.

More than many other fields of sociological study, military sociology is interdisciplinary. It draws on history, psychology, political science, and economics to meet the demands of multiple audiences beyond academia including military personnel and policy makers. An applied approach to research also sets military sociology apart from many other sociological fields. Enduring themes in military sociology include: motivation, cohesion, and effectiveness in combat; military professionalism; civil–military relations and citizenship; organizational changes within the military institution; and changing demographics of military personnel including issues of population diversity. In response to the ongoing conflicts in Iraq and Afghanistan, fought by multinational forces, as well as cultural changes in civilian society, military sociologists and their various audiences have become more concerned with changing military roles and strategies such as peacekeeping, counterinsurgency, and nation building; the changing roles of women and homosexuals within the organization; the effects of service on veterans and their families; and the involvement of reserve forces to meet the demands of ongoing conflicts.

Foundations of the Interdisciplinary and Applied Approaches

Although sociology was established as an academic discipline in the United States by the 1890s, an analysis of the growth of military sociology at the end of the twentieth century (Boëne, 2000) indicated that only about 5% of identified works were published before 1942. Boëne attributed the slow growth of the field largely to ideological liberalism, a meliorist orientation to social problems within the discipline, and war weariness after World War I. We would add to this the absence of a standing army during peacetime. Early contributions to the social science study of the military were by psychologists, historians, and political scientists, providing a foundation for the interdisciplinary orientation of military sociology, although they emphasized less sociological objects and units of analysis. On a micro-level, psychologists focused on individual abilities and behavior, contributing to aptitude testing and the understanding of effectiveness. On a macro-level, political scientists examined war as a component of the process of international relations, such as Charles Merriam's project on the causes of war, conducted at the University of Chicago, which led to Quincy Wright's (1942) seminal study of war. Not until sociologists were involved during World War II was much attention paid to the military as a social institution, an organization, an occupation, or a profession.

By the mid-twentieth century, the field of military sociology was dominated by Americans. The United States mobilized large numbers of social scientists, including academic sociologists during World War II. The pattern of interdisciplinary collaboration was established because the problems studied extended beyond the bounds of any single academic discipline. The emphasis on enlisted ranks and ground combat forces emerged in response to the nature and size of the mobilization during a mass-force era of military combat. Social scientists were mobilized explicitly to help manage the army and the war, orienting military sociology toward organizational and small-group processes rather than more macrolevel concerns, with an emphasis on policy applications for the research at army level rather than generating national policies regarding the army and other services.

Motivation, Cohesion, and Effectiveness in Combat

Not all sociologists were mobilized in research roles during World War II. Contributions by others who applied sociological skills to their military experiences, such as George C. Homans's (1946) observations of social relations on a small warship, which contributed to his conceptualization of exchange theory, and Tamotsu Shibutani's (1978) study of demoralization in a company of Japanese-American soldiers greatly enriched the field of military sociology. In 1946, *The American Journal of Sociology*, the major sociological journal of that time, published a special issue titled *Human Behavior in Military Society*. Included in this issue were Arnold Rose's study of military social structure, Alfred Lindesmith's observations of the effects of their status in service on the self-esteem of teachers, and August Hollingshead's article on adjustment to army life and to subsequent civilian life. Sociologists from other specialties continued to enrich the field by using the military as a venue for research and theorizing in the post-World War II years and into the twenty-first century.

Supporting both social research and personnel management, the landmark study of World War II reported results of experiments and surveys conducted by the Information and Education Division of the War Department. Among the topics included in the four volumes of *Studies in Social Psychology in World War II*, including the two-volume *American Soldier* studies authored by Samuel A. Stouffer et al. (1949a,b), were cohesion, leadership, primary groups, morale, race relations (the army was still racially segregated), communication, and persuasion. This study established the foundation of the research agenda of sociology and social psychology for many years. The power and thrust of this study served to focus attention on the enlisted personnel and shaped quantitative methodology in sociology as a whole. Thirty-five years after the publication of *The American Soldier*, *Social Psychology Quarterly*, the major journal in sociological social psychology, published an issue devoted to the impact of this work. Just as the U.S. military had adopted psychological selection and classification tests after World War I, the use of survey research to inform personnel policies continued after World War II.

Military Professionalism

Unlike previous military conflicts in U.S. history, World War II was not followed by demobilization (Burk, 2001). After the war, the United States, its allies, and adversaries maintained sizable forces, reflecting the new bipolar tensions in the international community produced by the Cold War (Segal and Segal, 2004). While the manpower to maintain these standing armies was frequently supplied by conscripted forces, the focus of social scientists shifted to the officer corps and military professionalism with publications by Samuel P. Huntington (1957), a political scientist at Harvard University, and Morris Janowitz (1960), a sociologist at the University of Michigan on the nature of the military profession and its relationship to the state and to society. Research on the professions was becoming a central theme in the sociology of occupations, and Huntington and Janowitz were not the first to examine the military through the professional lens. Prior to publication of their books, Norbert Elias published the first of an intended three-part series of articles examining the development of the officer profession in the British navy in 2007[1950]. Sociologists in other nations applied the questions raised by Huntington and Janowitz to militaries in their own nations. The focus of the developing definition of a profession included identifying the particular expertise of its practitioners, the responsibilities, status and authority attributed to the profession, and a strong group identity with autonomous regulation of access and discipline.

While mid-century conceptions of professionalism emphasized the active-duty officer corps, the challenges of the more technologically complex twenty-first century military suggest questions about expanding the definition of military professional to include well educated and technically proficient career-oriented enlisted personnel. Additional questions reflect the changes in the sociology of professions, the extent to which specialization in the armed forces requires recognizing each branch as a separate profession, and the degree to which reservists with other employment should be considered military professionals (Abbott, 2002).

Civil–Military Relations and Citizenship

Scholars in the mid-twentieth century attempted to describe the structural relationships between modern military forces and their host societies. Among the most important of these were Mills's (1956) *The Power Elite* and Lasswell's model of *The Garrison State*. Issues of the relationship between the military, the state, and society became even more of a concern following World War II. Civil–military relations continued to hold a place on the sociological agenda, even as the research focus returned to the enlisted soldier. Involvement through participation in militia units, mobilization and conscription, and a linkage between military service and citizenship had been an expectation of male citizens since the American and French Revolutions (Kestnbaum, 2002). In the United States, perceptions of inequality in the conscription process that placed the burdens of fighting the Vietnam War disproportionately on the poor drove a debate on ending conscription and manning the military force with volunteers. Economists held a central position in the discussion of whether labor market dynamics could replace conscription in meeting the manpower needs of the Cold War military. The decision was made and the 1972 defense appropriation provided funds for the establishment of an all-volunteer military force. The United States announced the end of peacetime conscription for the first time since World War II in January 1973.

As they had during World War II, the U.S. armed forces conducted and funded behavioral science research to support the challenge of maintaining a large standing force with volunteers. Although the service research units had emphasized psychology and the measurement of aptitudes since World War II, they reincorporated sociology and the study of attitudes. Military sociology grew as the military research units funded research in-house and at universities.

Organizational Changes within the Military

The shift to an all-volunteer force in the United States was a reflection of an international trend away from conscription, and reflecting this trend military sociology began to reconsider the nature of military service and its relationship to society. With Moskos's (1977) formulation of institutional and occupational models of the military, the focus of military sociology returned to enlisted personnel. Moskos suggested that military service was being transformed from a values-based vocation to a job motivated by economic benefits. This had implications for understanding both the individual soldier and military organization (Segal, 1986a) and affected both the military's recruiting efforts and sociologists' research on identity concepts. Moskos's conceptualization and many of its dimensions of change dominated the military sociology research agenda for more than a quarter of a century, as nations around the world abandoned conscription in favor of volunteer forces (Haltiner, 1999) and scholars applied Moskos's models to their own nations (Moskos and Wood, 1988).

As the U.S. Army was restructured after the end of the Cold War, military bases were reorganized. A new aspect of the relationship between the military and civilian society was added to the research agenda. We learned that communities around military bases have less racial inequality in employment and less racial segregation in housing than similar communities without the military influence. We also learned that gender discrimination in employment, as measured by higher female unemployment, lower female wages for all women, and lower returns to human capital investments, is higher in communities where the military is a major presence in the economy (Booth, 2003).

Changing Nature of Military Conflict

In addition to manpower changes, military organizations had to respond to the changing nature of military conflict. Moskos's formulation posited that occupational militaries would focus more on constabulary operations than conventional interstate wars, as Janowitz had hypothesized for military professionals following World War II. During the Cold War period following World War II, the principal antagonists (the United States and the USSR) and their allies maintained conventional mass-force structures while the 'middle powers,' countries such as Canada, the Netherlands, the Nordic countries and smaller countries, adjusted to the shifting demands of peacekeeping missions under the auspices of the United Nations. Cold War peacekeeping doctrine emphasized impartiality, minimal force, and host nation consent. Impartiality excluded the major nations since they were likely to be interested parties in any area of the world in which conflict occurred (Moskos, 1976). The United States did get involved on a continuing basis in peace operations conducted under auspices other than the United Nations (Segal and Segal, 1993).

With the end of the Cold War and the collapse of the Soviet Union and the Warsaw Pact, the center of gravity of military sociology shifted to Europe with a focus on changing the missions of military forces from conventional interstate wars to a broader spectrum of operations including strategic peacekeeping and nation building. Military budgets in many nations decreased and the size of military forces also decreased significantly. The major powers became more involved in peace operations at the same time that nations with more pacific security policies, such as Japan and Germany whose military roles had been limited at the end of World War II, were encouraged under new international norms of burden sharing to become involved in multinational peace operations (Segal and Kurashina, 2007). Military operations became less about conventional forces representing recognized states with similar allies facing similar adversaries on a defined battlefield, and more concerned with containing nonstate actors such as insurgencies and terrorism. These changes have been reflected in the field of military sociology.

Technology has also altered the military and military sociology. In addition to visible changes in war-fighting technology, communications technology has changed our perceptions of war and relationships between society, soldiers, and their families back home. From war correspondents in World War II, whose reports were reviewed by military censors before appearing in print the next day or in a newsreel the following week, to same day headlines and film from Vietnam on the evening news, to reporters embedded in military units filing their stories in real time from Iraq and Afghanistan, communications technology has changed the connections between civil society and the military. For the soldiers and their families, communications have progressed from mail with long delays between writing and receiving letters, through telephones and faxes, to frequent and widespread access via the Internet (Ender and Segal, 1998). In addition to the potential for distracting the war fighter with concerns about family struggles at home, communications technologies raise issues with information and mission security.

Changing Demographics in the Force – Race, Gender, and Sexual Orientation

The Vietnam War brought an increasing awareness in the United States of the effect that social trends were having on the military and broadened the subject matter of military sociology. Military units during World War II were segregated by race and gender. Minority soldiers, sailors, marines and airmen, and all women were limited in the positions available to them in the mid-century military. Manpower needs led to the desegregation of army units during the Korean War, but civilian society in the United States and the U.S. military experienced racial tensions during and after the Vietnam War. Even after the turn of the century, there were concerns about equal access to opportunity and equitable distribution of the demands of military service on the basis of race. Race was not as much of an issue in other Western industrial nations, but gender integration was a general concern. Women had served in the U.S. military during World War II and worked in the civilian labor force to keep the economy running and to support the men fighting overseas. After the war, middle class wives returned to their homes. It was another quarter century before female participation in the civilian labor force

and the demands of an all-volunteer force motivated the military to incorporate women into nontraditional roles. With the end of conscription, the U.S. military needed to incorporate racial minorities and women into the military in order to meet recruiting goals, and military sociologists added gender integration to the research agenda.

Moskos's institutional/occupational formulation suggested that women would increasingly be integrated into the military on an equal basis. Major advances toward equality in the numbers and roles of women in military service have taken place both in the United States and in other nations (Segal, 1995). Other dimensions reflecting increasing concern with diversity include continuing concerns with racial equality (Moskos and Butler, 1996); increased attention to the intersections of race, class, and gender (Booth and Segal, 2005; Moore, 1996, 2003); and emergent concerns with sexual orientation integration (Scott and Stanley, 1994).

In 1992, U.S. presidential candidate Bill Clinton promised to end a long-standing ban on homosexual men and lesbians serving in the U.S. armed forces. The change was resisted by military leaders, politically and religiously conservative organizations, and members of Congress. Research conducted at that time showed that some of the NATO allies similarly had policies that banned homosexuals from service, some allowed them to serve openly, and others did not care. The research also showed a significant gap between policy and practice (Segal et al., 1994). In 1993, the Clinton administration agreed to a policy that allowed gay service members to serve as long as they did not reveal their sexual orientation or engage in homosexual acts: a policy known as Don't Ask, Don't Tell (DADT). In 2010, the U.S. Congress voted to repeal DADT, once the President, the Secretary of Defense, and the Chairman of the Joint Chiefs of Staff certified that openly gay men and women serving would not harm military readiness. The 1993 debates involved considerable testimony by military sociologists, and led to an increase in the amount of research done on gays in the military. In 2010, the Secretary of Defense appointed a Comprehensive Review Panel to advise him on how the ban was to be lifted without impacting negatively on military performance. Again, military sociologists figured prominently in the review. DADT was repealed on 10 September 2011. Research conducted on the impact of repeal after 1 year showed that none of the negative consequences that had been anticipated by opponents of repeal had occurred (Belkin et al., 2012).

Reserve Forces

Reserve units in the American military had not been activated during the Vietnam War. Rather, a conscription system that deferred college students and burdened less advantaged populations fueled social unrest in the United States that was manifested in other nations as well. Following Vietnam, resources and tasks were redistributed among the active and reserve U.S. forces and the National Guard within the concept of a 'total force' that would require activation of reserve components to support future military missions. This allocation of essential mission support activities to reserve and National Guard units continued during the downsizing after the end of the Cold War.

While military forces were downsized, active contingency operations for humanitarian and peacekeeping purposes expanded, straining the capacities of the active duty military. Three approaches were taken to meet the increasing demands: maintaining a standby conscription system, increasing the use of reserve forces, and outsourcing. Jobs which required military competence and status were performed by military personnel while civilians were hired to fill positions that did not require military expertise or authority, and ultimately, deploying both active duty and reserve forces more frequently and for longer period of time than is optimal for military effectiveness (Korb and Segal, 2011). Just under 25% of the current U.S. Department of Defense workforce is composed of civilian contractors hired on a contingency basis. While civilian contractors have been used to support military operations since before the Civil War, the use of civilians to offset downsizing of active duty forces during a period of active deployment is unique. Military sociologists are beginning to explore the implications of having large numbers of noncombatant civilian contractor personnel who are exempt from military discipline colocated with military personnel in a combat zone (Kelty, 2009).

With the post-Cold War downsizing of the active force, nearly half of the army's combat force was in state-based National Guard units. The first challenge facing the reorganized total force was Operation Desert Shield/Desert Storm on the Arabian Peninsula in 1990. At the height of that conflict, about one-fourth of the personnel in the combat theater were Army Reserve and National Guard personnel, more than 73 000 in total. The bulk of the deployed reserve units served support functions such as transportation, medical, and military police units. The National Guard combat brigades that had been intended to join active duty combat divisions were judged unprepared for combat, and programs were developed to improve future deployability of National Guard combat troops.

By the mid-1990s, the army began deploying small numbers of reserve component personnel overseas for 6-month deployments in support of contingency operations. On the basis of a 1994 experiment, for example, American infantry participation in the Multinational Force and Observers in the Sinai Desert in support of the Camp David Accords, was shifted from active infantry battalions of the 18th Airborne Corps to National Guard battalions. With America's invasion of Iraq in 2002, the role of reserve personnel shifted from participants in contingency operations to participation in continuous operations subject to multiple longer deployments of a year or more. Increased reliance on reserve units has required more research to address the distinct concerns of reserve component personnel, their families, and their civilian employers.

Effects of Service on Service Members and Families

One concern drawing particular attention after 10 years of active conflict is the physical and mental well-being of the troops, many of whom have experienced multiple combat deployments. Post-traumatic stress disorder and high suicide rates among returning U.S. military personnel have returned

reentry stress to the research agenda as it was following the return of Vietnam veterans.

Veterans benefits and postservice outcomes such as education, employment, and earnings have been on the military sociology agenda throughout the all-volunteer era. The primary finding of this research has been that men who served during World War II or the Korean War benefited from their service when compared with their civilian peers who did not serve. Veterans of later conflicts have not been shown to experience the same benefits. The life course perspective, a major perspective in the larger sociological community, has been used to clarify the processes by which military service affects postservice trajectories (Wilmoth and London, 2012).

Following World War II, Reuben Hill (1949) published a landmark study of the stress that military service imposes on families. Twenty-first century sociologists in Europe and the United States continue to study family stressors and their influence on service member readiness and retention. While the conscripted force of World War II through the Vietnam War was primarily composed of young single men, the all-volunteer force of the later twentieth and twenty-first century is older and more likely to be married than in earlier years, particularly when reserve forces are considered. Sociological research has informed changes in policy and management practices to address the conflicting demands placed on service members by the military and their families (M.W. Segal, 1986b), the needs of family members that demand support from the military, and the effects that family members have on service member readiness and retention (Bourg and Segal, 1999).

Research has consistently shown that service members marry younger than their civilian peers, have first children earlier, and have larger families. Racial differences in marriage rates and stability are significantly lower in the military than in comparable civilian populations (Lundquist, 2004). More attention has also been given to the effects of being in a military family on child and spouse well-being and spousal employment issues as the multiple deployments to combat zones have strained family members' health and challenged employment.

Military Sociology as an Academic Discipline

Not until the 1960s, more than half a century after sociology departments were established at major universities, did military sociology emerge as a viable academic field. Charles Coates and Roland Pellegrin, of the University of Maryland, published the first textbook on military sociology in 1965. An organizational infrastructure in military sociology began with the establishment of the Inter-University Seminar on Armed Forces and Society (IUS), a small group of American scholars from several universities with interests in military sociology who met periodically to discuss their research, first at the University of Michigan and then at the University of Chicago. Since then the IUS has grown to an international and interdisciplinary group of more than 600 scholars, military officers, and students from over 35 countries around the world that meet biennially. Additional support for the study of military sociology came from the Research Committee on Armed Forces and Society of the International Sociological Association that began to bring military sociologists from a number of nations together every 4 years at the World Congresses of Sociology, and evolved into the Research Committee on Armed Forces and Conflict Resolution. In 1986, scholars concerned with military sociology in Europe formed the European Research Group on Military and Society (ERGOMAS). Through themed working groups and a biennial conference, ERGOMAS fosters interdisciplinary and international collaboration on the relationship between the military and civilian society.

Growth in military sociology corresponded with increasing fragmentation and specialization in sociological publications, as well as a reluctance among major sociological journals to publish articles on war or the military in the wake of the Vietnam War. Two specialized journals, *Armed Forces and Society (AF&S)*, published by IUS, and *Journal of Political and Military Sociology (JPMS)* were established to provide outlets for the increased research and writing in the field. JPMS has recently become a research annual, and the publishing field has been expanded with the establishment of *Res Militaris*, an international electronic journal, reflecting advances in publication technology.

Articles published in these journals, and more recently in major sociological journals, reflect long-term research traditions, as well as the field's responsiveness to the changing needs of the military, and changes in sociological theory and society as a whole. Recognition of sociological contributions to the military mission is apparent in the increasing number of courses in military sociology offered and the numbers of military sociologists being included among the faculty of military academies internationally (Caforio, 2000).

The processes of group dynamics continue as active areas of study, but conceptualizations changed. Cohesion and effectiveness were important concerns during World War II and important topics on the early military sociology research agenda. While early research emphasized social cohesion among homogenous troops without demonstrating a positive impact on performance, more recent conceptualizations emphasize task cohesion based on contributions to common goals (Segal and Kestnbaum, 2002). In the 1990s, the questions about the relationship between the conscripted military, the state, and the society raised by Huntington and Janowitz that motivated international research at that time and in the early years of the volunteer force were reframed within the context of the larger sociological interest in social context. New questions considered the extent to which the culture of the military diverged from that of its host society (Feaver and Kohn, 2001), and once again motivated international comparative studies. Research showed that the American military culture, like other militaries and other professions, is distinct yet consistent with the broader culture within which it is embedded and which it defends. Another set of questions concerns the nature of the relationship between the military institution and the state, and between military service and citizenship, and the implications of those relationships both nationally and internationally (Kestnbaum, 2002).

Research on military conscription continues to be a high priority as nations around the world discuss ending conscription among concerns about the equity of less than universal service and the manpower demands of ongoing conflicts.

While military sociology maintains a strong interdisciplinary orientation, changes in the larger discipline of sociology influence the questions asked by military sociologists. One example of this is Moskos's response to postmodernist theorizing in the sociological community. Like his earlier conceptualization of the shift from a values-based institutional model to an economically based occupation, Moskos proposed a shift from a modern to a postmodern military. Some of the dimensions specified reflect microorganizational aspects such as gender roles and the relationship between the military and service members' families. Macrolevel dimensions such as changes in mission and force structure did not correspond to components of the institutional/occupational (I/O) model. Like the I/O model, the postmodern model has been applied to militaries in many nations (Moskos et al., 2000) finding that, while militaries vary in the degree to which they would be classified as modern, none qualify as postmodern under this template. Principal critiques of the postmodern military concept are that the analytic structure is inherently positivistic, not postmodern at all, and that no structured military can be truly postmodern by the nature of postmodernism (Booth et al., 2001).

Military sociology continues to influence military policy and practice. Research informs changes in social programs in support of veterans and service families, in manpower management issues such as gender integration and issues of equity, and in actual operations. One example of sociological theory applied to combat is the use of social network theory in the mission to locate Saddam Hussein (Reed and Segal, 2006). The primary professional organization for military sociologists, IUS, includes many active-duty and reserve military professionals among the scholars contributing to conferences and in publication. Research has expanded beyond ground combat forces to include naval and air forces.

As an academic discipline, military is still a small, yet growing, subfield within sociology. A growing number of colleges and universities offer courses or programs studying the military from a sociological perspective. As nations in Central and Eastern Europe consider ending conscription, redesign the relationship between the military and their new democratic governments, modernize and professionalize the military, and address issues of gender integration and service members' families, interest in the applied aspects of military sociology has grown. In spite of renewed interest in military sociology inspired by the Global War on Terror and a decade of involvement in active combat by U.S. troops, the center of gravity of the field appears to have moved from North America to Europe since the end of the Cold War.

Abstract

Ensuring that the military fight in the interests of government and society has been a major issue throughout history. The political structure that is generally seen as the model of success is the state, and in particular the modern democratic state. The theories underpinning this claim tend to be highly normative and context dependent. Based overwhelmingly on a strongly entrenched Western-centric narrative of historical development, much social science has struggled to reorient itself to understand and address the current conflicts and political disorders that rack the globe.

The relationship between military, war, and politics is an important issue for four reasons. First, war can make or break societies and their governments. Second, war, understood as the application of violence, is often believed to possess a special, inherent dynamic that makes it prone to escalation and loss of control. Third, the military's special skills set – the management of force – might make them prone to advocating and implementing inappropriately violent solutions to political problems, whether domestic or international. Fourth, the tendency of bureaucracies to pursue self-interested ends imbues a military bureaucracy with a special danger: it has a uniquely powerful potential to making its voice heard and getting its way. These concerns about war and the military mean that societies (or those that matter in society) seek to establish ways of embedding the military within political structures that ensure that it only fights in the interests of government and society.

The issue of controlling war and the military achieved special salience in the modern world with the rise of a particular form of political organization: the state. The state established the military as a distinct bureaucracy. It also developed the capacity to mobilize manpower and push military technological production to a degree that made wars unprecedentedly destructive. The relationship between state, war, and military was characterized by an inherent instability. War and military were instruments of state that continually bridled at the leash of state control. The modern academically informed debates about stabilizing the relationship were, on the one hand, developed under the shadow of the world wars and the spectre of nuclear weapons. On the other hand, these debates have not been free from strong normative and empirical Eurocentric influences that stretch back further in time. The leading ideas underpinning modern discussions about the proper polity, the nature of war, and the special position of the military are predominantly of a post-French Revolutionary, nineteenth century vintage. As the modern theories associated with military, war, and politics cannot be divorced from historical and normative context, it is useful first to outline the historical master narrative that frames modern understandings, before briefly identifying the main post-Second World War theories. This broader context helps explain the difficulties much analysis and theorizing is encountering in the face of the challenges thrown up by a globalizing world since the end of the Cold War.

The Military and the Rise of the State

The emergence of the military as a bureaucracy is regarded as indissolubly linked to the rise of the European state as the preeminent form of political organization. Modern understandings of this dual development have been governed by a master narrative of European history that was created in the nineteenth century and which persists in its basic outlines to this day. In the high middle ages, there was no distinction between those who fought and those who governed. The nobility across the continent was fragmented into many thousands of competing entities. All claimed extensive political rights to independent power. The three key expressions of independence lay in their direct claims to the proceeds of taxation, the administration of justice, and the right to resort to force. Military power was organized around the noble household. Nobles sought to retain followers, usually drawn from extended family and local region, who in return for being provided for, rendered military service. Military assistance did not exclude other forms of service, but because it produced the hard foundation of economic and political power, it was predominant. Shrewd power politics could translate into greater economic power, and thus the amassing of greater relative military power. Capitalizing on these opportunities was greatly enhanced by improving economic conditions, especially from the twelfth century onward. Greater agricultural yields invigorated trade and increased the money in circulation which in turn aided social stratification. Military service came to be remunerated with money. A monetary nexus strengthened the traditional bonds of political loyalty between men, but also facilitated the emergence of a new group of nonpolitical men, known as mercenaries, who fought for financial gain.

Here an opening, or even a necessity, was created for the state to emerge and establish order in societies hitherto wracked by conflict and instability. Enterprising rulers, so the classical story goes, could employ apolitical mercenaries to bring the excessively politicized, fractious, and independent-minded nobility of Europe under control. Economic growth created both a pool of manpower and the monetary means to

pay them. What was required was an entity to extract fiscal resources from society and organize, direct, and pay military manpower: the state. The key to extraction lay either in the application of absolutist power politics or in the forging of a deal between rulers and the emerging middle classes who benefited from the order imposed by the rulers' armed force (Tilly, 1990; Porter, 1993). In the states that achieved the greatest degree of domestic stability and permanence, this deal formed the basis for the emergence of representative parliamentary democracies (Downing, 1992). In the older military historical literature the process of gaining the upper hand over the nobility was helped by a structural tactical weakness: the nobility fought on horseback and this was less effective on the battlefield than disciplined massed infantry (Delbrück, 1920–1923). Later accounts accord a prominent role to technology: the cavalry and castle strongholds of the nobility were particularly vulnerable to the new gunpowder weapons that appeared in the fifteenth century (Parker, 1996; Rogers, 1995). Despite the varying emphases, this narrative has a teleological and deterministic quality about it. Economic growth, extractive tax mechanisms, and military technology combined to form a self-reinforcing mechanism that produced a stronger and stronger state. A diversity in economic potential might give certain regions and states structural advantages over others: compare, for example, the success of early modern England and the Dutch Republic with the crisis ridden and faltering Holy Roman and Spanish Empires. None of these political communities managed to escape the basic logic of state formation.

The Nation-State and the Emergence of Civil–Military Relations

State fiscal weakness could exacerbate one key issue: maintaining the loyalty of the mercenary military. Their purely economic motives meant they would serve the highest bidder and, when none was available, they possessed the means forcibly to extract through plunder the resources required for their own upkeep. The 30 Years' War (1618–1648) has long provided the most telling illustration of the damage mercenaries and their enterprising captains could do to a country. In response, states strengthened their fiscal grip to create permanent, standing armies. The provision of stable employment and regular pay went some considerable way in obviating the desire for soldiers to seek alternative employers or self-employment. Payment by itself, however, did not provide total assurance of loyalty in such a dangerous occupation as the military. The undesirability of the work had reinforced the practice of recruitment, often by impressment, from the untrustworthy but abundantly available dregs of society. Retention issues thus remained. But they now shifted from the danger of fighting for another state or plundering for private gain to wholesale desertion. Draconian discipline, lifelong service and physical separation of the soldiery from society through the building of barracks were measures increasingly applied in the eighteenth century to keep armies forcibly together.

In this narrative, the issue of loyalty was only resolved by the nation-state. By the time of the French Revolution, monarchical state structures were sufficiently developed to mobilize, organize and discipline sizable military resources. A sense of national identity, however, massively boosted war-fighting potential by permitting universal conscription of a population loyally committed to national defense and, possibly, international aggrandizement. The introduction of the *levée en masse* in 1793 and the more than 20 years of major war that Republican and Napoleonic France managed to sustain, proved the practical effectiveness of the concept of national loyalty bolstered by the organizational and coercive capacities of the state. National conscription was adopted across Europe, usually hesitatingly by monarchies fearful of revolution, but wholeheartedly by progressive regimes who saw citizen-soldiers as their natural instrument of self-defense. With each new experience of major war – one only has to recall 1870, 1914, and 1939 – the strength of national feeling pleasantly surprised anxious conservative regimes while confirming the expectations of the progressive democracies. The association of armed forces with nation and state has remained a powerful one: the citizenry in the modern state-studded developed world remain overwhelmingly wedded to the idea that proper and effective military forces, whether conscript or volunteer, should be organized by states and function best if motivated by national loyalty.

As states pacified the territories within their borders, wars were turned outward and became 'international.' Two effects are associated with this development. Internationally, the success of nation-states in mobilizing military resources is seen as destabilizing. Sovereign states feared each other's war-fighting potential, but by increasing their own forces in response they only increased the nervousness of others. Thus a shared feeling of insecurity set off a process which resulted in the phenomenon of arms races so clearly observable before the First World War and also during the Cold War. Arms races are often cited as a key factor in causing the First World War (Hermann, 1996). The state system and the ensuing instability (termed 'security dilemma') also inspired the major modern international relations theory of Realism (Morgenthau, 1948; Waltz, 1979). Domestically, the pacification process at first permitted the military to separate itself from the civilian social and political spheres. The military emerged as a distinct state institution and bureaucracy which was dedicated to fighting the state's international wars and which also functioned as the latent, ultimate sanction for maintaining domestic order. The highly influential work *On War* by the Prussian general and military philosopher, Carl von Clausewitz (1780–1831), is predicated on a separation between war (military) and politics (civil). He associates war with a particular activity, force, whose special properties require and justify management by a specialized, carefully trained profession, which acts on behalf of and under the watchful eye of a government and which represents the higher interests of state and nation (Clausewitz, 1976).

Militarism and Total War

Clausewitz also first theorized the phenomenon of escalation in war. If war is about the use of force and if the warring parties want to prevail, then their interaction dictates that each side seeks to use more force than the other. War is therefore in

principle about making the enemy defenseless, preferably through an immediately overwhelming offensive blow. In the later nineteenth century, this understanding of war provided a theoretical underpinning to the practical professional processes of military force generation and operational planning. The distinctive demands of war and war preparation professionalized the military and set it increasingly apart from the civilian sphere. The belief that war had to be fought offensively with overwhelming means conspired with the unstable international environment to make the military 'a state within the state' which threatened civilian political supremacy. Critics coined the label 'militarism' in the 1860s to describe this danger (Berghahn, 1984).

Publicly, the concerns about the political implications of military demands found a focus in the intensely political debates about the issue of conscription. Military professionals (joined by political conservatives who feared the insurrectionary potential of conscripts) favored enlisting regulars and tightly regulated long-serving conscripts. Those fearful of state and society succumbing to militarism argued that a system of universal short-service conscription of citizen soldiers would provide an effective hedge against both domestic militarism and international threats. For much of the nineteenth century, debate raged across continental Europe about the relative merits of the long service professional versus the short service citizen soldier. Blessed by their fortunate geographical position, the UK and US (with the brief interruption of the Civil War) avoided much of these disputes and settled on the compromise of maintaining small regular armies that neither threatened the domestic constitutional order nor imposed the burden of conscription on society.

The experience of the First World War suggested that the military were not simply a state within the state but that it could become the state itself and erase all civil–military distinctions. Harbingers of later developments could be seen in the Austro- and Franco-Prussian wars of 1866 and 1870–1871 during which Prussian chancellor Otto von Bismarck's political preferences famously clashed with Prussian chief of the general staff Helmuth von Moltke's visions of military necessity. By 1917–1918, the German military went much further with the silent institution of a military dictatorship led by Generals Erich Ludendorff and Paul von Hindenburg. Militarizing pressures intruded on the political processes in all countries at war and all governments struggled to varying degrees with maintaining civilian supremacy. The unprecedented mobilization of resources between 1914 and 1918, which included the novel phenomenon of a 'home front,' even threatened to make war an end in itself.

Modern warfare thus raised immediately pertinent questions about the appropriate national constitutional order that would put nation-states in the best position to survive war. 'Total war' was the most radical conceptualization to emerge in the interwar years. Ludendorff, who had led German forces to defeat in 1918, summed up the idea in a popular 1935 book. He took it as given that the international system was marked by the struggle for national survival. The total war for survival required the total mobilization of the nation under the organizational aegis of the totalitarian state. War, Ludendorff wrote, was no longer, as Clausewitz had claimed, a continuation of politics, but politics was a continuation of war by other means (Ludendorff, 1936). Such militarist conceptualizations received significant scholarly input from German academics, like the sociologist Hans Freyer and the constitutional lawyers Carl Schmitt and Ernst Forsthoff. A variation took hold in the USSR. The life-and-death struggle between capitalism and communism dictated a total mobilization of socialist society which took advantage of the unity between party, proletariat and state.

The liberal democracies were not immune to this debate. The term total war, for example, had originated in France during the First World War. However, the democracies feared and resisted militarization of their constitutional order. The US sociologist Harold Lasswell famously warned in 1941 of the danger "that we are moving toward a world of 'garrison states' – a world in which the specialists on violence are the most powerful group in society" (Lasswell, 1941: 455; Friedberg, 2000). Although the democratic powers came out of the Second World War victorious and with their democratic institutions unimpaired, militarist pressures did not abate. The Cold War demanded a permanent state of war preparedness and war, if it were to break out, would likely see the use of nuclear weapons. A real threat remained that the military and war could overwhelm politics in peacetime and in wartime.

The Victory of Democratic Control over the Military and War

This is the dark empirical background against which the seminal modern contributions of the 1950s, 1960s and early 1970s to the analysis of the relationship between military and politics and war and politics should be situated. Samuel Huntington (Huntington, 1957) and Morris Janowitz (Janowitz, 1960) put forward theories on the forms of civil–military relations which most effectively protected against foreign threats without endangering democracy at home. Morton Halperin (Halperin, 1974) and Graham T. Allison (Allison, 1971) analyzed the bureaucratic politics of self-serving government agencies with a view to identifying the best ways of assuring effective policy process. Bernard Brodie and Thomas Schelling worried about nuclear escalation and sought to develop effective strategies of conflict (Freedman, 2003). Alfred Vagts (Vagts, 1959) and Gerhard Ritter (Ritter, 1954–1968), with pertinent personal experience of recent German history, provided historical accounts of the phenomenon of militarism (Berghahn, 1984). To this list of influential authors, one should also add Clausewitz. In the highly successful 1976 English translation of *On War* by Michael Howard and Peter Paret, Clausewitz's work emerged as the seminal text on war as a political instrument (Honig, 2007).

This body of literature was overwhelmingly normatively based. In contrast to the earlier writings on total war, it did not overtly question the desirability of a democratic political order, nor refrain from expressing an abhorrence of war. It also accepted that war possessed a unique and unchanging nature and that the military domain constituted a special sphere of activity, distinct from the civilian and the political. The association of war with escalation fueled fears that nuclear war could perhaps not be managed. For all the assiduous application of novel and imaginative social

scientific methods, the literature struggled to arrive at clear and indisputable findings on how the relationship between (nuclear) war, military, and politics was best managed. While a social scientific consensus proved elusive, a normative consensus emerged that war was better avoided altogether and that it was the role of prudent government policy to promote this.

The military's main role settled on acting as a deterrent. This put the military in a clearly subservient position which, pacified with relatively generous defense budgets and relatively independent management, it on the whole accepted. The growing destructiveness of weapons technology diminished the need for vast armies of conscripts. So the move away from manpower-intensive to technology-intensive war preparation, underpinned ultimately by a relatively cheap nuclear weapons inventory, made the demand for total mobilization redundant. Constitutional pressures thus abated and civil–military relations could to all appearance be adequately managed by the prevailing structures of civilian ministerial oversight and parliamentary budget control.

Preparation for war did not overwhelm the state and its democratic-capitalist order. The needs of modern, technology-intensive war, on the contrary, emphasized the importance of creating a select, specialist profession of 'managers of violence' (in Huntington's subtle adaptation of Lasswell's phrase). Even the instances in which the military were used – Vietnam being the most prominent case in point – it did not threaten the primacy of democratic political control. Despite the emergence of an influential narrative that the Vietnam War was lost as the result of a failure by the political leadership to define clear objectives and accept military professional demands to follow through the logic of war by escalating to success, defeat was an understandable outcome justified by the overall political context which carried the risk of a local war escalating into a global nuclear holocaust. Studies noted that, with respect to the administration of US civil–military relations during Vietnam, 'the system worked' (Gelb and Betts, 1979) and that the military were generally much more cautious than their political leaders about committing to the use of force (Betts, 1977).

Some concern persisted about the self-serving inclinations of military bureaucracies and there was an extensive debate in 1980s about the allegedly pre-emptive and offensive preferences of military-professional organizations (Miller et al., 1991). Official US policy statements also indicated that the military continued to prefer strategies that emphasized a speedy use of overwhelming force (the 1984 Weinberger and 1991 Powell doctrines). By the end of the Cold War, a strong confidence had nonetheless set in that 'mature democracy' had overcome the traditional challenges the military posed to politics. The apparent success of a particular stage in Western political development was further underlined by the contrast with the developing, 'third' world countries where military coups appeared an endemic problem. And even in the 'second,' communist world the totalitarian system seemed to creak and crack at the seams because of the social and financial burden imposed by maintaining a totalitarian system that was locked in an exhaustive arms race with the capitalist West.

Post-Cold War Challenges

Established theories and paradigms did not prepare the social sciences well for the end of the Cold War. Overwhelmingly state-centered, the prevailing discourses were suddenly confronted with wars that seemed to escape from state control and that saw paramilitaries and other irregulars engaging in unconventional and often highly brutal warfare. Some scholars, like Israeli historian Martin van Creveld, argued that a new age of 'low-intensity conflict' had dawned which would spell the end of the state and its conventional military (Van Creveld, 1991). The wars in Yugoslavia, in west, central and east Africa, and later also in Iraq, Afghanistan, and Syria, not to mention the 9/11 terror attacks against the United States, heralded the return of fundamental questions. First, if wars no longer originated with states and if existing states could not get them under control, were they no longer political, but instead driven by fundamentally different considerations and motivations, such as religion or criminality? Or were wars still political but nurtured by different, possibly novel forms of political organization and motivation? Second, had the nature of war changed or was war, as it had so often done in the past, merely changing in outward character? Third, in what ways should the conventional military adapt? Were new forms of organization and new operational approaches to war required, in addition to new equipment and technology? Were established understandings of military professionalism and the strict separation between civil and military, between politics and war, still fit for purpose? In short, not only did the emerging threats exhibit a different relationship between the society sustaining the organizations that conducted war, but the relationship between war, military, and politics in the developed world seemed in line for fundamental reappraisal and reform.

A number of ambitious attempts were made to map the issue of political order and change and the relationship with war. With the power of the state to bind together, control and protect society in doubt, the search was on for a different, or a previously underrated, principle of order. Samuel Huntington presented a controversial theory that claimed that the major 'civilizational' wars of the future would take place along the 'fault lines' between the world's major religions (Huntington, 1997). Azar Gat adopted a revitalized sociobiological approach according to which the extended kinship group of the nation harnessed and civilized the human drives for food, shelter, and procreation which, he claimed, had the potential to create a more peaceful democratic world (Gat, 2006). Philip Bobbitt laid out a future 'constitutional order' marked by the transition from nation-states to frontierless 'market states' which would spawn their own forms of conflict, weapons, and vulnerabilities (Bobbitt, 2008). The heterogeneity of threats and the elusiveness of final outcomes also saw a rise in the popularity of connecting the idea of 'risk society' with war. In an argument similar to Bobbitt's (though perhaps less assured), the bureaucratization of war in states and international law was seen to have created its own subversive enemies which, in response, called forth novel technological and strategic responses (Rasmussen, 2006; see also Coker, 2009). Scholars from the left were drawn to more pessimistic, economistic explanations. They saw the privatization and commercialization that marked the 'globalizing' world mirrored in 'new wars'

in which private enterprisers brutally pursued their own unrestricted commercial gain (Münkler, 2005; Kaldor, 2012).

These accounts continued to subscribe to the idea that war was an instrument, though it was no longer seen as directed by a narrow state-rational, political instrumentality. They did not directly engage with the issue of the nature of war, even though they suggested that war was a very different animal which had changed more than just the color of its skin. The direct debate on the changing nature of war, however, had an unsatisfactory quality about it. There were those, like Colin Gray, who forcefully claimed that war would always remain war (Gray, 2005). Others, like Van Creveld, equally forcefully asserted the contrary (Van Creveld, 1991, 1999). Underscoring the centrality of Clausewitz in this debate, both sides proffered wildly different interpretations of his thinking which generally sidestepped the philosophical intricacies of the phenomenon's definition.

The uncertainty of political change and the unclarity about war's changeability in scholarly treatments likely encouraged a tendency to cast the debates about civil–military relations and the conduct of war in the developed world in familiar terms. The fear of military coups had disappeared, but concerns about a widening gap between civil society and the military re-emerged from time to time, as did questions about the efficacy of political control over the military. Receding threat levels and budget pressures meant that armed forces shrunk significantly in size and, with fewer and fewer exceptions, they did away with conscription and became all-volunteer establishments. Views differed on the effect. Militaries generally favored the move as it accorded with traditional standards of professional self-image. Some, usually without the military, claimed that the military profession had come to distinguish itself in little from civilian professions and was firmly embedded in society's value system and bureaucratic practices. However, others worried that the military's (conservative) political preferences might prove out of step with civil society and lead to misunderstanding and tensions over policy aims and societal support. Conversely, civil (and political) society might misunderstand the special nature of the military's expertise in violence and make demands the application of force could not deliver. The historically unprecedented dwindling in the number of civilians, and especially politicians, with direct experience of war and the military fueled a concern that the military would be used too readily for inappropriate purposes. A technological 'Revolution in Military Affairs' (RMA) created a worry that remotely guided precision weaponry and electronic intelligence gathering might make war 'virtual' and turn it into a spectator sport, taking place far away from a domestic audience's (and even its military's) direct experience (Ignatieff, 2001; McInnes, 2002). In a worst case, military professional self-confidence could enter into an unholy alliance with military technological prowess and popular domestic clamoring for overambitious foreign military adventures (Bacevich, 2005).

Human rights abuses and especially terrorism did tempt grand coalitions of Western countries to launch a series of increasingly ambitious military interventions. Since state failure and collapse was regarded as the main cause of these troubles, nation-building emerged as the main goal of intervention. But the wars in Afghanistan from 2001 and Iraq from 2003 in particular showed how unfamiliar and surprisingly resistant the local human and political terrain was. These long wars called into question the efficacy of established military professional operational approaches to war and political understandings of nation-building. Multipronged 'whole of government' or 'comprehensive approach' seemed an obvious necessity. Lining up government agencies, and a host of nongovernmental agencies, from many countries proved no easy undertaking. Militaries proved highly resistant to taking on new and unfamiliar 'nonviolent' roles.

Ambitious but vague political designs, limited resources and military professional myopia led to civil–military tensions over both Iraq and Afghanistan, as it had in Yugoslavia in the 1990s. Civilian supremacy was never called into question, but neither was military professional independence. The conviction persisted that war and politics were essentially separate spheres and as the military had no business meddling in politics, politicians had no business meddling in war. Closer civil–military cooperation and coordination at the highest levels of government found advocates in academia, with some arguing that politicians needed better to understand the immutable nature of war (Strachan, 2013) and others that "political leaders must immerse themselves in the conduct of their wars" (Cohen, 2002: 206). Failing that the military would fight as well as they could but their actions would take place in a political vacuum and likely lead to unhappy or imperfect outcomes. On the other hand, the military puzzled over the question whether traditional approaches to war still worked (Kaplan, 2013). First Iraq, then Afghanistan followed the same scenario. The magnitude and complexity of the task overwhelmed weak civil–military coordination and an uncertain use of force. The interventions drifted toward a limited focus on development of an indigenous capacity to provide security.

The social sciences seemed to play catch-up for much of the time. Students of state formation could not easily produce immediately applicable strategies for rebuilding failed and collapsed states. Development aid experts faltered in the face of the unprecedented challenge of administering aid in support of an international war effort. Students of bureaucratic politics struggled with proposing ways of overcoming the interagency rivalry between unrivaled numbers of national and international agencies and non-governmental organizations (NGOs). Finally, strategic studies' specialists did little better than resurrect a counterinsurgency literature that had been developed – with decidedly mixed results – in an era of colonial wars when standards of applying force had been rather more permissive. In a recognition that much of the available academic expertise was perhaps too Western-oriented, the US military attempted to recruit specialists from anthropology, a discipline that had hitherto played little part in informing military policy and strategy.

Recent experiences underline once again that the relationship between military, war, and politics is not only a highly complex, but a changeable phenomenon. Contemporary democratic states may offer the best model for achieving relatively harmonious relations between military, government, and society and ensuring that the military act in the interest and

with the support of society. Democratic society may have freed itself from the spectre of direct military involvement in domestic politics. Democracies may also be most sturdy of states, capable of withstanding most serious threats because of their rootedness in popular support and participation. The apparent peacefulness of the domestic democratic order and the international order between democracies make this a tempting model for humanity. The theories which explain why this is so and how this came to be, however, tend to be colored by strong normative convictions and are rooted in a particular justificatory historical narrative. The wars between the West 'and the rest' over the past 20 years illustrate that effective alternative narratives exist. They make intelligible and justify other forms of political organization which are capable of generating, supporting and sustaining militaries that relate to government and society in very different ways from the Western model. Given the strength and stability of the established Western paradigm, coming to analytical terms with these unfamiliar wars fought by unfamiliar polities is likely to be a slow process.

Abstract

J.S. Mill's main contributions to social science lay in three areas: political economy, political philosophy, and the philosophy of social science. The major works identified with these three fields are *Principles of Political Economy*, *On Utilitarianism*, *On Liberty*, *Considerations on Representative Government*, and his *Logic*. Although educated in classical utilitarianism – the view that the criterion of moral and political rectitude was the pursuit of the greatest happiness for the greatest number – Mill is famous for his critical adjustments to it, expressed particularly in his essay *On Liberty*, where he advocated political arrangements that maximize the freedom of the individual. In many of his works he stressed and explored the significance of historical processes – sensitivity to which had been absent from his utilitarian predecessors' aspiration to create a purely deductive social science, and increasingly from the liberal political economists who would claim his legacy. Mill's iconic status as a liberal has made his intellectual legacy a site of fierce ideological contestation.

John Stuart Mill was born in London, on 20 May 1806. His precocious education – famously described in his *Autobiography* (1873) – although commonly held to have inculcated him with utilitarian principles, and certainly intended by his father to prepare him for a career as a social and political thinker and reformer, was grounded in the classics. His father started him with Greek at age three, and his education was much wider than that of most modern social scientists. He spent a year in France in 1820–21 before beginning a career in the civil service, following his father's footsteps at India House, London Headquarters of the British Indian civil service.

The young Mill was introduced by his father to the Philosophical Radicals, a largely extra-parliamentary grouping of Benthamite utilitarians on the more radical wing of those seeking parliamentary and administrative reform. However, his underlying philosophical position was undergoing a reappraisal. In his *Autobiography*, Mill describes an emotional crisis at age 20 that had important intellectual dimensions and was finally resolved only following the death of his father in 1836. Establishing some distance from his father and his upbringing, he claimed, liberated his thinking from Benthamite utilitarianism, his differences with which were first outlined in a series of articles on 'The Spirit of the Age' in the periodical *The Examiner*. An important aspect of his new position was the ideal of self-cultivation (which his own *Autobiography* sought to encourage). He was inspired in his exploration of the imagination and emotions by his relationship with Harriet Taylor, a married woman whom he met and fell in love with in 1830. To her he also credited considerable influence in the intellectual development of his arguments. Despite this awakening of feeling, Mill rejected intuitionism as a basis for philosophy and was committed to extending the experiential methods of the natural sciences to the social. The new dimensions in his thinking did, however, stress the limitations of the associationist psychology that had informed his own upbringing and introduced ideal-regarding criteria – standards that looked to the fulfillment of certain ideal principles – into the predominantly want-regarding and consequentialist character of his inherited utilitarianism. Furthermore, Mill increasingly recognized the thick historical texture required for an understanding and appraisal of social and political institutions. Through his father's Scottish education and his teacher Dugald Stewart, Mill had access to the thinkers of the Scottish Enlightenment – David Hume, Adam Smith, William Robertson, and Adam Ferguson – who had developed sophisticated accounts of what would today be called historical sociology, then termed philosophical history. Mill's interest in this can be seen as early as his essay *Civilisation* (1836).

There were new influences that he also acknowledged. He devoted an essay to S.T. Coleridge sympathetic to the latter's concern to institutionalize historically acquired learning and cultivation in a national clerisy – a kind of secularized church establishment. Alexis de Tocqueville's two volumes of *Democracy in America* were reviewed by Mill for the *Westminster Review* in 1835 and 1840 and had a profound effect on his thinking about the need to manage the political effects of the historical movement to more democratic societies. Auguste Comte, whose sense of history as a process of rational amelioration survived (albeit frailly) in Mill, although he rejected Comte's more elitist policy implications. Impressed as Mill was by Tocqueville's account of local democracy in American townships, and his claim that democratic culture was the inevitable future for European commercial polities, Tocqueville's worries about egalitarian mediocrity reinforced Mill's concerns, already voiced in *Civilisation*, about the stifling of individuality, energy, and dissent in the emergent mass societies. Although America had abolished an aristocracy of taste or intellect, this had not eradicated deference, which Mill now saw being abjectly paid to 'public opinion (which) becomes in such countries a species of religion and the majority is its prophet.' A continuing concern for Mill, henceforth, was, as he put it in his review of Tocqueville's work, 'that there should exist somewhere a great social support for opinions different from the mass.'

Mill's commitment to radical politics itself faltered at times following disillusionment with the Radicals' Whig allies in the Reform Parliament of 1832. The major focus of his political activity at this time became a new radical periodical, the *London and Westminster Review* (1835). It was from the early 1830s too that he began work on his *A System of Logic*, book six of which is devoted to the logic of the moral, i.e., social sciences.

 http://dx.doi.org/10.1016/B978-0-08-097086-8.61092-9

Mill recognized that since the application of the principle of utility required an assessment of consequences, a knowledge of social and historical context and process was needed to make such assessments. However the utilitarianism of Bentham and Mill's father, James, had attempted to model, understand, and explain political phenomena deductively, drawing out the implications of utilitarian psychology, rather than attending to the specific cultural and historically contingent features of society, an omission for which the historian Macaulay famously had lambasted Mill senior's aprioristic, deductivist *Essay on Government*. Mill's exposure to the tradition of historical thinking in the Scottish enlightenment of the eighteenth century, theorizing as it did the effects of large-scale social changes, for example, economic and social mobilization, on human reasoning processes and ultimately on social conventions and forms of political association, meshed well with the concerns of his more recent contemporaries about the emergence of democratic society. Mill's *Logic* analyzes the methods appropriate to the different branches of science – Mill's view being that the only secure ground for deductivism is the assured existence of the uniform operation of physical causes, an assurance that is not actually present in the moral, as we would say social, sciences. In Book VI *On the Logic of the Moral Sciences*, Mill discussed the extent to which the human sciences diverged from the natural. His discussion has become a point of departure for much teaching and theoretical reflection in the social sciences ever since.

Outlining the possibility of a social science, Mill subjected to criticism two alternative methods that he called the geometric and the chemical methods, by analogy with sciences already treated earlier in the *Logic*.

The geometric method that was pursued by his father in his ill-fated *Essay on Government* was an attempt to deduce the optimum form of government from certain posited axioms about the selfish motivations of human beings. This cannot work because deductive operations presume a uniformity that cannot cope with the quintessential sociopolitical circumstance of multiple, simultaneous, and conflicting causes impinging on a given social or institutional context. Geometrical deduction is not even yet mechanics, which, crude though it is, can at least cope with this multiplicity of forces.

The chemical method is the attempt to infer causal laws from the interaction of complex entities at (at least) one remove from their underlying physical causes. Mill's thought here seems to be that if real causes take place at the level of physics, 'chemical' phenomena represent epiphenomena that are related *in some systematic way* to those (hidden) underlying real physical causes, and that by a complex of observation and deduction, the chemical properties of physical elements might be derivable at this level. The limitations of this method are that it can only apply where the observed phenomena are *invariantly* related to underlying causal properties – as in the case of chemical compounds whose properties relate systematically to those of their constituent elements. Since the underlying causes of social phenomena are many and various and not elemental or invariant in their operation, it is not possible to treat political facts in the manner of chemical facts nor to induce from experiment or observation any reliable causal regularities. Mill instances the attempt to answer the question whether regulating imports is conducive to economic prosperity or not. Even supposing two apparently similar polities pursuing different policies in this respect would not constitute a test case, argues Mill. The reason is that different trade policies are not ultimate 'properties of Kinds' but presuppose a whole raft of differences in opinions, habits, and so on, which might themselves influence the success of the economy, with or without free trade.

For Mill, 'true' causation operated only at the level of local physical events. A human science that sought to base itself on causal generalizations, therefore, must ultimately be grounded in the discovery of physiological causes. However, he recognized these were too far below the level of the visible 'general circumstances of society' that he sought to understand, for the latter, at least in the present state of knowledge, to be unpacked in terms of the former. In the meantime, he thought, empirical induction about the effects of circumstance on human character formation (which he called 'ethology'), although it does not yield full causal knowledge, could produce 'empirical laws' of greater or lesser range and accuracy, and which might certainly be useful presuppositions against which to consider the likely consequences of policy initiatives. Such empirical laws yielded what he called (following Comte) both 'uniformities of coexistence' (social statics) and 'uniformities of succession' (social dynamics). Although neither the deductive nor the inductive method was sufficient in itself, such confidence as we can have in deductive conclusions can be derived, Mill thought, from "collating the conclusions of the ratiocination either with the concrete phenomena themselves, or when this is unobtainable [as in the case of social science], with their empirical laws." This combination of deductive and inductive reasoning brought to bear on even very complex phenomena, whilst it could not achieve the level of predictive accuracy available in the natural sciences, could prove extremely useful to the "wise conduct of the affairs of society" (*Logic* VI, ix, §§1,2). It might even, in time, be linked with or 'resolved into' the real causal laws at the level of physiology, so effecting a complete union of the social with the physical sciences. Yet even if this were not fully achieved, there was, Mill insisted, the possibility of constructing a science of society or what he called 'that convenient barbarism' – sociology.

Following his *Logic*, which was a considerable publishing success, Mill returned to political economy. His father had taught him economics in his childhood, and he had even published in the subject at age 16. His *Essays on Some Unsettled Questions in Political Economy*, written in 1830–31, now found a publisher (1844), and he settled down to the composition of the *Principles of Political Economy, with Some of their Applications to Social Philosophy* (1848). Not only (as the subtitle indicates) did he regard economics as inseparable from the rest of social philosophy, he also regarded the relationship between economics and social theory more widely considered as being the most important part of it. Whilst composing it, Mill was painfully aware of the Irish potato famine, and the impact of economic orthodoxies on its course. Seeking to avoid specific polemical issues, Mill was nevertheless concerned to stress that political economy was "far from being a set of maxims and rules, to be applied without regard to times, places, and circumstances" (*Hansard* v.190, 1525). Thus, although in pure economics he regarded himself as a follower of Ricardo, he distanced himself from those who took Ricardo to have

established a purely deductive school. Historians of economic thought disagree as to precisely how to characterize this relationship and who these economists might be (see Hollander, 1985: vol. II, pp. 914ff.). It is clear, however, that Mill regarded good economic method to combine both deductive and inductive operations, and in policy stressed the importance of knowledge of local conditions – such as those in Ireland or India – in applying that method. Economic science, he thought, operated under those limitations applying to the social sciences generally, outlined in the last volume of the *Logic* – deductions were only reliable if the generalizations that generated them were the result of physical causes, and even then only if other causal effects did not intervene. Neither of these conditions, in his view, obtained in economics any more than in the rest of social science. This also informed his view of the limited role that mathematical or formal modeling might be expected to play in economics – for without certainty or quantification such precision was likely to be misleading.

Mill's insistence on subordinating economic analysis to policy consideration is clear in his famous chapters on socialism in the *Principles*. These underwent considerable development in the first three editions (1848, 1849, 1852), under the influence of the European revolutions of 1848, which had reopened debate on the subject, and of Harriet Taylor (whom he had married in 1851 following the death of her husband). Originally skeptical about cooperation, Mill now discussed the ideas of Fourier as a supposedly superior synthesis of the ideas of Robert Owen and Saint-Simon, which overcome earlier worries about the lack of incentivization in cooperative schemes. He came to see the emergence of cooperative forms as both an evolutionary possibility within capitalist economies and – once population could be voluntarily controlled and inequalities moderated through inheritance tax – a desirable social form in which individuality and moral progress, far from being under threat, could flourish better than in conventional economies.

Such themes integrate with the political writing to which Mill returned, at the end of the 1850s, producing a trio of important essays, long in the making: *Utilitarianism*, *On Liberty*, and *On Representative Government*. These worked out his concern to articulate a conception of progress consistent with utility, as a part of which he sought to support diversity of opinion and to protect social and political institutions from the effects of mediocre uniformity – whether deriving from the middle classes' social conformism or a socialist-inspired working-class movement.

Utilitarianism articulated a modified defense of the principle of utility into which Mill introduced significant modifications. The first was the claim that in addition to the various dimensions of utility analyzed by Bentham, and contrary to the latter's claim (made notorious by Mill himself) that 'pushpin was as good as poetry,' it was possible to distinguish higher from lower qualities of pleasure. Amongst the higher pleasures were those of altruism, the cultivation of the higher feelings and of the intellect. Quality as well as quantity was to be given weight in seeking to apply the utilitarian criterion that actions were 'right in proportion as they tend to promote happiness.' This constituted a rejection of Bentham's insistence on the integrity of individuals' subjectively expressed preferences and introduced what many have seen as an elitist, ideal-regarding element into utilitarianism. Mill's second innovation was his claim that the principle of utility should be deployed as a criterion of moral or social principles, practices, or institutions, and *not* applied directly to regulate individual actions. The distinction has since been refined and elaborated as that between rule utilitarianism and act utilitarianism, although Mill does not make the distinction in these terms: although justice is grounded in utility, direct appeals to utility cannot be used to overthrow (any but?) the hardest cases.

Classical utilitarianism was premised on the integrity of each individual's experience of utility. Each was to count for one and no more than one, and each was the best judge of their own utility. Mill's two modifications, perhaps worryingly, allow privileged judgments to be made, capable of overturning the subjective claims of the individual; but they also allowed judgments about progress to be made that did not rest purely on increasing the quantities of pleasure.

Issues about progress underpin what is perhaps Mill's most famous work – his defense of liberty. In *On Liberty*, Mill formulated what he disarmingly called a "very simple principle," one he had introduced in all but name, in his *Principles of Political Economy*. There he remarked that "there is a circle around every human being, which no government, be it that of one, the few or the many, ought to be permitted to overstep" (*PPE*, Vxi, §2). Mill's principle was that "the sole end for which mankind are warranted, individually or collectively, in interfering with the liberty of action of any of their number, is self-protection, that the only purpose for which power can be rightfully exercised over any member of a civilised community, against his will, is to prevent harm to others. His own good, either physical or moral, is not a sufficient warrant" (Acton, 1967: 72–73).

Mill's principle has become an icon for liberals and occasioned a huge literature, both academic and polemical. The academic controversy has centered around two issues: whether Mill's defense of the principle of liberty was consistent with his claimed loyalty to the principle of utility, and whether his defense of the integrity of the sphere of individual liberty is ultimately coherent.

Mill denied that his defense of liberty involved any appeal to abstract right distinct from utility. The latter remained the 'ultimate appeal on all ethical questions.' It was, though, 'utility in the largest sense grounded on the permanent interests of man as a progressive being' to which one had to appeal, and not the mere maximization of existing preferences. This invoked his attempt in *Utilitarianism* to introduce the qualities and refinement of pleasure and not just its quantity as a utilitarian criterion. Briefly, the connection Mill makes between the defense of liberty and 'enlarged utility' is that utilitarian progress (beyond mere quantity) presupposes innovation, and innovation presupposes (though it is not guaranteed by) liberty. Liberty of thought and speech could generate and promulgate new ideas and test old ones, avoiding the static mediocrity that he feared so much. Liberty in the sphere of private action enabled experiments in living from which might emerge new and more beneficial social forms, new forms of domestic partnership and cooperative production in the sphere of the economy being two such examples. In this view, liberty

could be justified in instrumental terms as a means to a social progress defined, or definable, with reference to utility ('in the largest sense…'). However, Mill's enthusiasm for liberty – redoubled in the closing passages of *On the Subjugation of Women* – his celebration of what he disarmingly calls the 'intrinsic worth of individuality' and the cultivation of the personality as a 'noble and beautiful object of contemplation' – appeals to an autonomous aesthetic ideal that has seemed to many commentators to go well beyond the instrumental role claimed for it in his more programmatic statements.

Mill also had great difficulty sustaining the boundaries of the 'sphere of private action' that he attempted to mark by distinguishing 'self-regarding actions,' which were not to be collectively interfered with, and 'other regarding actions,' which were, in principle, candidates for legislative or social restraint. The viability of this in turn involved distinguishing between actions that merely 'affect' and those that 'affect the interests of' others. But the notion of interests, whilst clearly different from wants or preferences, is a notoriously difficult one to deploy – particularly for liberals – without establishing paternalistic claims over individuals' preferences.

Mill's working through of this principle is for some an object lesson of the sensitivity required in the application of philosophical principles to areas of policy, for others revealing of a residual paternalism.

Considerations on Representative Government, Mill claimed, embodied the principles to which he "had been working up during the greater part of my life." It was certainly, amongst other things, an attempt to show how his commitment to liberty as a part of a revised conception of utility could be embodied in political institutions. It revealed an acute historical sensitivity to the broad circumstances that made representative government possible, to the generation of supportive dispositions in the population and to those processes that might imperil it – the race, as he put it, between democratization and education. Representative government is fixed firmly within the presuppositions of a progressive, national, metropolitan state, and for all Mill's celebration of diversity, he evinces little enthusiasm for sustaining the contributions to diversity of relict regional or national cultures such as those of the Celtic-speaking nations.

Once representative government is possible – which is not the case for all stages of human development – Mill considers there are two criteria by which government should be judged: efficiency and education. The first seeks the optimum 'use of the existing good qualities' in the population; the second seeks to augment the virtuous qualities in the population at large. These can be seen as a version of two principles widely seen as central to many nineteenth-century thinkers: stability and progress. Much of the work is a consideration of various political institutions in light of the trade-off between these two principles. Two examples may suffice: those of voting and local government.

Like all utilitarians, Mill rejected abstract or natural rights, and did not derive the vote, any more than liberty, from such principles. The right to vote was for him grounded in the important necessity of ensuring that every individual – even, as he later publicly argued, women – had an institutional expression through which they could safeguard their interests. But this did not entail the privacy, equality, universality, or unlimited domain of the franchise. All of these were to be assessed in consequentialist terms, through their contribution to utility. Consequentialist judgments are sensitive to the empirical circumstances of that which is being judged. Mill acknowledged that privacy of the ballot box might once have been necessary to avoid undue pressure from employees, landlords, or social superiors, but the danger now, he thought, came from individuals regarding the vote as an expression of their selfish wishes. Public voting would, he thought, have the advantage of requiring voters to justify their decisions to their fellows, incentivizing them to decide on grounds of public reason rather than private interest. Consequentialist considerations also informed his thoughts about the electorate. Though all adults have a prima facie claim to the vote for protection, equal voting is not necessarily conducive to the best outcome – part of which is to make the best use of the talents available. Mill advocates an educational test (at least partly to encourage self-improvement), disfranchising those receiving welfare benefit, and proportional representation and plural voting for university graduates and professional classes. This ensured that minority and educated opinion would at least be heard in Parliament, exercising benign influence on less-informed representatives, and mitigated the potential for majority tyranny. For similar reasons he opposed the mandating of representatives. Finally, Mill regarded representative bodies as incompetent to draft or engage in detailed amendment of legislation, which should be left to commissions of experts. Mill thought such considerations enabled a distinction to be drawn between 'True and False Democracy.' In True Democracy, the role of the People is 'strong enough to make reason prevail but not strong enough to prevail against reason.'

Mill's discussion of local government stresses the educative role it can play in giving the inexperienced scope for political participation in a limited sphere where they cannot damage great national interests. Devolution must not, however, be so great as to exclude the interest of at least some of the educated from whom lessons might be learnt, nor, he thought, should it ever escape the superintendence of the national government.

Mill sat as Liberal MP for Westminster – a notoriously radical seat since the 1780s – in the 1865–68 Parliament, his candidacy provoking huge demand for cheap popular editions of his *Political Economy*, *Liberty*, and *On Representative Government*. True to the spirit of his observations in *On Representative Government*, he refused to pledge – or indeed campaign – prior to the election. The most famous cause he espoused during that period was to seek – albeit unsuccessfully – to amend the 1867 Reform Bill so as to grant votes to women. This became a major cause for him during the rest of his life, and his *The Subjection of Women* (1869) has become one of the canonical texts in the study of women's political emancipation.

Harriet Taylor had died in 1858 in Avignon, where Mill subsequently spent half of each year until his own death on 7 May 1873. Harriet's daughter, Mill's stepdaughter, Helen, acted as Mill's secretary and arranged the publication of a number of his papers after his death, including the *Autobiography* and the *Chapters on Socialism*. In the latter, Mill pursued themes explored in the later chapters of his *Principles of Political Economy*, although with even greater open-mindedness as to the possibility of one form or another of socialism proving itself superior. Although he thought revolutionary socialism and a centralized economy both unjust and 'chimerical,' and that even temperate, though extensive, forms of socialism were 'not

available as a present resource,' he recognized the high moral values implicit in some of these and was firmly of the opinion that various socialist schemes 'have a case for a trial.' For him though, the criteria to be applied in such a trial were essentially those of the development of human character. Mill recognized the irresistibility of the advance of democracy, the implications of which were still working their way through society and which, when they had done so, would penetrate to 'the very first principles of existing society' – in which he included private property. Yet, whilst accepting this, his concern to balance values that the mass of the people might not yet share is one of the central tensions in his work, informing what has come to be seen as his central preoccupation: the defense of liberty.

Mill's *Principles of Political Economy* enjoyed huge – almost canonical – status in the middle of the nineteenth century, down to the marginalist revolution associated with Jevons and Marshall. It is now no longer of technical interest to economists but remains an important chapter in the history of economic, and social and political, thought. That part of his *Logic* devoted to the philosophy of the social sciences remains an important statement of a particular approach in sociology. Mill's political writings have a more ambiguous legacy. Political science now takes forms – and has preoccupations – Mill could not have foreseen; as a result, his *Representative Government* now has a less practical character than he might have hoped for it. *On Liberty*, however, is still often read in the spirit in which it was written – as a statement of moral and political philosophy to be considered as a success or failure in terms of the arguments advanced there. Perhaps what would have been most satisfying of all to Mill, his own character as a public moralist, the ideal of personal character formation, and his complex and nuanced treatment of political nationality have reemerged recently as an acknowledged central preoccupation of his work.

Abstract

Millennialism is defined as a general term synonymous with millenarism and millenarianism and chiliasm. Its provenance and transmission via Judaism precedes an outline of the history of Christian millennialism in which premillennialism, belief that the Second Coming will precede the millennium, and postmillennialism, the thesis that the millennium will result from human effort before the Second Coming, are distinguished. Militant millennialism in Europe is exemplified, preceding discussion of the nineteenth century growth of mass movements. Predictions of dates are exemplified from the history of the Seventh-day Adventists and Jehovah's Witnesses. Examination of various sects indicates that the relative deprivation thesis, which postulates that religious belief is a compensation for various forms of felt deprivation, does not account for the appeal of millennialism to its entire social constituency. Divergent responses to the problem of cognitive dissonance, experienced when prophecy fails, are compared with reference to the Seventh-day Adventists, Jehovah's Witnesses, the Exclusive Brethren, and the Catholic Apostolic Church. Reference is made to the incidence of millennialism in other major religious traditions. Examples of third-world so-called millennialism raise the question of whether these phenomena are autochthonous (that is, indigenously inspired) or result from Christian influence. Mass movements of a magical orientation are compared with militant millennial cults, and the role of millennialism in forging new bases of social identity and in raising group consciousness is indicated.

Millennialism (derived from the Latin term, millennium, which means literally 1000 years) is the belief that a prolonged period of bliss is a future prospect, usually expected to commence after catastrophe which will end the present dispensation and perhaps the world itself. Salvation and survival into the new era will be confined to those who believe this prophecy and conform to certain stipulated demands of faith and morals. Millennialism has inspired numerous movements throughout the world and given rise to outbursts of intense social unrest, but has also created new patterns of social consciousness.

The Term Millennialism

The terms millennialism, millenarism, and millenarianism are more or less synonymous, although some writers (Harrison, 1979) have sought to distinguish millennialism as scholarly theological concern with prophetic exegesis, and millenarianism as applicable to social movements preaching the imminence of the millennium. This distinction, however, is not observed generally. The term chiliasm (Greek *chilioi* – a thousand) is also employed in reference to social manifestations of belief in the early outworking of prophecy.

Historical Provenance

Millennial ideas arose in Zoroastrianism which exerted an influence on Judaic eschatology in which it became a strong theme. Jewish apocalyptic literature linked the millennium to the expectation of a returning messiah, a king to save his people, and this association informed the expectation among early Christians that Christ would soon return to earth to rule over his kingdom for 1000 years. The concept gradually has acquired wider application to contexts other than the Judeo-Christian, and is used loosely to refer to a long period of time rather than specifically to 1000 years, but it is in Christianity that millennialism is most fully, albeit controversially, articulated.

Development in Early and Medieval Christianity

In Christian history, an assortment of New Testament texts, especially Revelation 20, have been cited alongside the Old Testament books of Isaiah, Daniel, and Ezekiel to provide both a sequence of events and allegorical reference points as a basis for a chronology for the prophesied millennium. Some early Church fathers and various heretical movements expected an imminent literal outworking of prophecy, and looked forward to indulgences and pleasures which they had hitherto denied themselves. Augustine changed Christian thinking by regarding the contemporary epoch of the Church to be the millennium, at the end of which Christ would return and establish the conditions of eternity. Millennial ideas did not disappear, however, and found expression in the theories of Joachim of Fiore in the twelfth century and in various heretical movements, and they received a new impulse from sects that arose in Reformation times.

Pre- and Postmillennialism

For later Christians, Daniel Whitby (1638–1726) formulated the position which became widely accepted, that the advent would occur at the end of the millennium rather than before, thus establishing a distinction between postmillennialists (who believed that the advent would follow the millennium) and premillennialists. Postmillennialists held optimistic beliefs about social progress and the diffusion of the Christian message through missionary activity, thus paving the way for the return of Christ. The designation 'millennialist' was henceforth applied to premillennialists, those expecting the imminent second advent of Christ. Among themselves, premillennialists differed about other matters, among which

were: whether the tribulation alluded to in I and II Thessalonians would occur before or after the 'rapture' of the saints (i.e., their being caught up in the clouds to join Christ); and whether the millennial kingdom would be established on earth (as believed by Jehovah's Witnesses) or in heaven (as maintained by Seventh-day Adventists). Most millennialists have been 'mortalists,' denying that man possessed an immortal soul.

The Development of Premillennialism

Millennialism has given rise to numerous episodes of fanaticism. After the Reformation, the 'open Bible' policy of Protestants gave millennial expectations common currency. Many movements inspired by expectations of the early fulfillment of prophecy have been of short duration, particularly those with adherents who took it upon themselves to take up arms to help bring the advent and the millennium about. Such were the Anabaptists who occupied the city of Münster in Westphalia in 1534, and the Fifth Monarchy Men who challenged the secular authorities in the 1650s in England.

Dating in Prophetic Exegesis

Millennialists have not depended on the secular calendar in affirming when the millennium would begin, but have often set dates. Only the most proximate dates have inspired active movements. Expected dates have been calculated by the choice of specific past events as the departure point for the outworking of chronology and the application of numerological principles. Those calculations concerning the fulfillment of prophecy generally have not coincided with the completion of the first or second millennia of the western calendar. Not all movements have committed themselves to predicting specific dates, and others have done so guardedly in recollection of the repeated scriptural warnings that Christ would come 'like a thief in the night.' Jehovah's Witnesses have been perhaps the most persistent in setting dates for the fulfillment of prophecy (having, formally or informally, at different times and successively harbored keen expectations of 1874,1914, 1925, and 1975). The Seventh-day Adventists, after the disappointed hopes of William Miller's predictions for 1843 and 1844, have abandoned date-setting, while the Christadelphians, although much exercised on the subject and disposed, especially in their early years (1840s and 1850s), to look for signs in contemporary political events to match biblical prophecies, have for a long time disavowed the possibility of acquiring accurate foreknowledge of the time of Christ's return.

The Size of Modern Millennial Movements

Whilst postmillennial orientations stimulated missionary and revivalist activity in the eighteenth century, particularly in North America, the pessimism implicit in premillennialism previously had inspired movements which operated in considerable tension with the state and the wider society, and these hostile movements usually were small and localized. Growth of literacy and improved communications in the nineteenth century allowed sectarian premillennialists to organize much larger, enduring, and widespread movements, some of which, by the end of the twentieth century, had followings counted in millions (e.g., the Seventh-day Adventists, Jehovah's Witnesses). As the need for better accommodation with modern society and the agencies of the state grew, so these sects became less aggressive and their insistence on the imminent end of the existing dispensation less strident.

The Social Constituency of Millennialism

It has been a general assumption that those attracted to millennial sects are not only pessimistic about general social conditions, but are likely to be drawn from disinherited social groups, and the relative deprivation thesis has been frequently invoked to explain their appeal. As a generalization this may be warranted, but by no means all of those attracted to millennialism have formed their views in socially or culturally disadvantaged circumstances. Prominent Protestant thinkers – Joseph Mede, the theologian, and the scientist, Isaac Newton, among them – were devoted to numerological exegeses of biblical prophecy. The initial leaders of the strongly adventist (premillennial) Catholic Apostolic Church included several Anglican priests and Church of Scotland ministers, and all but one of that church's 12 apostles were either lesser aristocracy or professional men. Several lay supporters were, or became, MPs or higher civil servants. The originators of the contemporaneous movement devoted to premillennialist prophetic exegesis (later known as the Plymouth Brethren), were clerics and ordinands, and local leaders were often men of some substance. Nineteenth century millennialism had an appeal which extended beyond the working class.

When Prophecy Fails

Millennial movements all face the prospect of the failure of prophecy, and examination of their history reveals diverse responses to this problem. Gager, following Festinger's study of a contemporary adventist cult (*When Prophecy Fails*, 1956) has contended that the expansion of early Christianity was attributable, at least in part, to the failure of millennial expectations (Gager, 1975). Believers sought to overcome the cognitive dissonance of failed prophecy by persuading others that they were not wrong: the next best thing to being proved right was to persuade others to join you and to accept your rationalizations for the error. The evidence on early Christianity is perhaps too sketchy to substantiate this contention, while Festinger may have studied too small and ephemeral a movement (in which he and his team constituted too influential a group) to warrant the comparison.

Two Responses to Failure

Even so, some millennialist movements have triumphed over repeated failure of prophecy, and have done so by various different strategies. Perhaps the most successful of contemporary millennial bodies, the Seventh-day Adventist Church, has flourished by cultivating an encompassing program of educational, dietetic, and therapeutic welfare in which to engage members' energies. This policy originated early in the movement's history, and has expanded despite the apparent inconsistency of devoting resources to welfare in a world due soon to

be overturned by the cataclysmic events supposedly foretold in the Scriptures. In contrast to this many-sided strategy to occupy the faithful, Jehovah's Witnesses, whose theology teaches that God's Kingdom is already established but not yet visible, seek to engage their following single-mindedly in the work of recruitment. This is a response to failed prophecy more or less on the Festinger model. By deploying their 'publishers' (the movement's designation of its members) in extensive house-to-house calls, the movement has developed a systematic method not only of winning new adherents but, perhaps more importantly, of involving members in the regular reaffirmation of their own commitment. The primacy of this latter function becomes apparent when it is acknowledged that at least 200 h of canvassing are on average expended by publishers for each additional new convert.

The Introversionist Response

The Plymouth (Exclusive) Brethren response to hope deferred has been a classic withdrawal from involvement in the wider society into a more introversionist position. The movement has ceased to proselytize: although still undertaking token public proclamation of 'the truth,' they are far from exhorting listeners 'to come and join us' – joining is not an option that is made easy. The Brethren, who regard their assemblies as already a foretaste of heaven, expect the Holy Spirit to guide all sincere Christians to them and their way of life. Maintaining communal purity has become a primary concern, hence the insistence on separation from the inherently evil world, and the diffidence respecting would-be converts. A less extreme example of the same shift of orientation from keen millennialist expectations to a more introverted position is also found among the Christadelphians.

The Demise of the Catholic Apostolics

Perhaps the most radical resolution of the experience of failed prophecy was that of the Catholic Apostolic Church. The Church confidently expected the advent to occur in the lifetime of its original 12 apostles, who were designated (by members who claimed the gift of prophecy) in the early days of the Church's formation in *c.* 1830–35. An apostle died in 1855, and a shocked church acknowledged that there was no brief to replace him. The last of the 12 died in 1901. Thereafter, the Church, according to its own rubrics, lacked legitimacy to ordain ministers. Eventually, in the 1970s, the last minister, ordained by the last apostle, also died. The self-prescribed denial of the competence to make new appointments virtually pre-ordained the demise of the Church if prophecy failed. A schismatic branch in Germany survives, the Neue Apostolische Gemeinde, in which designated prophets took a different view and nominated successors to apostles as they died.

Millennialism in Other Religious Traditions

The millennial theme represents a final outworking of history, in which the wicked are punished, and the righteous are saved in a process which is envisaged generally as involving severe tribulations. The term is applied loosely, however, and the constituent elements of millennialism, as manifested in Christian eschatology, are often absent in so-called millennialist movements in other religious traditions. In Judaism, the messianic element is strong, and has stimulated the emergence of messianic claimants. The most celebrated of these was Shabbatei Tzevi (1626–76), a self-styled messiah whose following, and that of his various successors, was widespread throughout the Middle East and Europe, and which persisted even after he recanted and converted to Islam. In Islam, the Shi'ite tradition of a hidden imam, due to return to lead the faithful in some future time, incorporates both messianic and millennial themes, but the rising of the Mahdi, Mohammed Ahmed ibn Seyyid, in nineteenth-century Sudan appears to have been a more explicit admixture of revolutionary political aims and religious fervor. The visions of future salvation, following a period of tribulation, found in the claims made in the Hindu tradition for Kalki, an avatar of Vishnu, and the prospect of the forthcoming troubled age of Mappo, in Mahayana Buddhism, have lacked the power to inspire significant social movements and scarcely qualify to be designated millennialist. The other-worldliness of Indian religion appears to render it inhospitable to millennialist themes. A more explicitly millennialist movement occurred in late nineteenth-century China, in the T'ai'ping rebellion, but this movement was influenced directly by Christian ideas.

Third World Instances

A wide assortment of religious uprisings among tribal peoples are often termed millennialist. Most of these movements are ephemeral. Some are openly militant, proclaiming either the early return of the ancestors and engaging in practices designation as nativistic, or claiming to be the true originators of all the innovative accoutrements of western civilization. Sometimes a messiah is promised as the savior who will usher in the time of prosperity and bliss, and the prophet harbinger of the new era may himself be cast in the role of messiah. The cargo cults of Melanesia exemplify the collective messiahship of the ancestors for whose return votaries practiced ecstatic rituals or sought to dance the new dispensation into being. The Ghost Dance of 1870 among the tribes of California and its more celebrated successor of 1890 proclaimed collective salvation once the ancestors were induced to return to practice the old ways.

Christian Influences in Third World Cases

Many of these movements were influenced powerfully by Christian millennialism. Christian missionaries were often clergy of fundamentalist persuasion, or were drawn from fundamentalist denominations: millennialism was a stock part of their message. The Kitawala movement in what is today Zambia, Zimbabwe, and Malawi was a radical and semi-politicized millennial cult which owed its inspiration to Watchtower preachers (later designated as Jehovah's Witnesses) of whom Joseph Booth, a sometime Seventh-day Adventist, was a conspicuously influential figure. Suggestions that the Tupinamba and Tupi-Guaraní tribes in South America who, as early as the mid-sixteenth century, were discovered to embrace a cult which taught that they might dance themselves to

weightlessness and be carried off to a promised land of deathlessness in the East, illustrated the possibility of autochthonous millennialism, uninfluenced by Christianity, may be discounted, since those who first reported this phenomenon were Jesuits.

Mass Magical Movements

Various Third World movements were designated readily as millennial even though all that they promised were miraculous therapies or new means for detecting witches. Such were the various Zionist sects of South Africa; the pocomania cults of Jamaica, which claimed to counteract obiah, so-called black magic; and the Lumpa Church of Alice Lenshina which fell victim to military intervention ordered by the Zambian government in 1964. These cults have operated essentially at the individual level, seeking to play very little part in inducing changes in social consciousness.

Revolutionist Movements and Social Consciousness

The more avowedly revolutionist movements have often enjoyed greater influence. Such was the case with the Hau-Hau movement among the Maoris which played a role in the Maori Wars; the Maji Maji Rebellion in East Africa; the afore-mentioned Kitawala movement in Central Africa in provoking the Chilembwe uprising; and the collective resistance movement among erstwhile mutually hostile North American tribes under Tenskwatawa, the Shawnee prophet. Millennialism has often served as an unwitting agency in raising the consciousness of tribal or ethnic identity, or of the need to transcend it in a wider cause. This appears to have occurred among Rastafarians in the West Indies, and more effectively among the Mahdists of the Sudan in the formation of a new state. Prospects of salvation as a chosen people in a new millennium caused Paul to declare that Christians were 'neither Jew nor Greek, bond nor free,' but a new people with a new collective identity.

Abstract

Charles Wright Mills was one of the most famous American sociologists of the mid-twentieth century. A public political intellectual, he wrote about the moral uneasiness of the post-War era. Mills's major works include a treatise on social psychology, a trilogy on the American class structure and power system, mass-market paperbacks on nuclear war and the Cuban Revolution, and his most famous book on the sociological imagination. In Mills's view, freedom and reason were being threatened in post-War America. He believed that through a particular way of thinking – what he called the 'sociological imagination' – individuals can better understand the meaning of their epoch for their own lives, and also become active participants in history making.

C. (Charles) Wright Mills (born 28 August 1916, Waco, Texas and died 20 March 1962, West Nyack, New York) was one of the most famous American sociologists of the mid-twentieth century. He was well known and widely read not only in the United States but also in Europe, the Soviet Union, and Latin America. His popularity was due largely to the sale, in the hundreds of thousands of copies, of his mass-market paperbacks. A public political intellectual, Mills delivered 'sermons' about the moral uneasiness of the post-War era to a nonprofessional audience of learned 'publics' by which he meant various groups of politically alert people (Aronowitz, 2012).

Mills's sociology is regarded as 'critical' not only because he exposed the underbelly of U.S. society in order to engender structural change but also because he ruthlessly critiqued the mainline sociology of the 1950s. As one of the foremost dissident intellectuals of the Cold War period and a particularly harsh critic of American foreign policy and national security strategy and of big business and mass society, Mills's thinking had an indelible influence on several generations of dissenters in sociology and the other social sciences. Toward the latter part of his career when he had become more of a political radical, Mills came to be seen as a spokesman for the New Left, the new generation of radicalized students, activists, and intellectuals.

Mills's sociology focused generally on two concerns: (1) the influence of social structure on personality and (2) the bureaucratization of modern society and the power relations it produces (Treviño, 2012). His scrutiny of the centralization of power in the hands of a few elites and the manner in which institutions shape the character of individuals enabled him to engage in a running critique of the types of uninformed men and women and repressive large-scale bureaucracies that prevailed in American mass society during the middle decades of the twentieth century.

Mills identified himself thoroughly as an 'American aboriginal' (Mills and Mills, 2000: 205). This notwithstanding, he held a blatant contempt of American influence and ideology, and was particularly indignant with those who engaged in what he called the 'Great Celebration' of U.S. society without addressing its cultural and political deficiencies. Despite Mills's anti-pro-America stance, he was nonetheless always deeply concerned with the preservation of democracy in the United States. He remained troubled that the U.S. was far less democratic than it should be.

Owing largely to his polemical writings, his moral-political 'preachings,' and the celebrity status he enjoyed outside academe, Mills frequently found himself at odds with many of his colleagues. In consequence, he was effectively ostracized from the sociological community. Mills's response to this exclusion was to become an academic outlaw and exhibit a brusque and choleric mien toward anyone in opposition to him. In contradistinction to most sociologists of the period, Mills, as a public sociologist, aimed to convey modern social science ideas to a broader audience outside the academy by employing a clear and vivid prose. Such were his ways of showing contempt for the routine canons of academe and what he referred to as 'the higher ignorance' of the received sociology of the time.

Personal Life

Mills was born in Waco, Texas on 28 August 1916 to a middle-class family of mixed English, Irish, and French ancestry. He grew up in Sherman, Fort Worth, and Dallas, and spent a few years in San Antonio. His later efforts to escape his Texas backwoods beginnings by immersing himself in urbane high-brow surroundings may partially explain why he saw himself and was treated by others as an 'outlander' in various aspects of his personal and professional life (Horowitz, 1983). Mills also rejected his parent's middle-class world, which he regarded as one of artificial politeness and simulated contentment. He did this by adopting the political ethos and persona of the radical nonconformist.

After graduating from Dallas Technical High School in 1934, Mills enrolled as an engineering student at Texas Agricultural and Mechanical College (A&M), which at the time was an all-male military compulsory institution. As a result of a particularly troubled freshman year at A&M, Mills developed an enduring "visceral negative reaction to militarism" (Geary, 2009: 61).

At the beginning of his sophomore year, Mills transferred to the much more cosmopolitan University of Texas (UT) at Austin, where, in 1939, he concurrently earned a BA degree in sociology and an MA in philosophy. During his senior year at UT, he wrote three essays on the sociology of knowledge. It was on the

strength of these articles, published by the two leading journals of American sociology, that Mills, at the age of 25 years, first came to the attention of scholars working in the areas of the sociology of knowledge, pragmatism, and social theory.

In the fall of 1939, Mills began doctoral training in sociology at the University of Wisconsin, where he continued his studies in the sociology of knowledge and pragmatism. During his final year there, he met and befriended Hans H. Gerth, an émigré from Nazi Germany, who had recently been hired to teach at Wisconsin. Gerth and Mills collaborated on two books: *From Max Weber: Essays in Sociology* (Weber, 1946), the first English translations of Weber's sociological writings, and *Character and Social Structure* (Gerth and Mills, 1953), the first social psychology textbook that considers the influences of institutional orders in shaping individual character.

In 1941, Mills accepted a position as assistant professor of sociology at the University of Maryland, even though he had not yet finished his dissertation, *A Sociological Account of Pragmatism*, in which he interpreted the careers and publics of the American pragmatist philosophers, Charles Sanders Peirce, William James, and John Dewey. Throughout his career, Mills maintained an interest in the social and intellectual values of pragmatism, which emphasizes the fusion of theory and practice, intellect and craft. For Mills, theory must always have a practical use and he regarded his sociology as a form of 'craftsmanship,' where knowledge is intrinsically related to social action.

With the involvement of the United States in World War II, Mills endeavored to avoid being drafted into the army. He was ultimately classified as unfit for military service due to chronic hypertension and well as a too high pulse rate. Mills was adamantly opposed to U.S. involvement in the War. Contrary to most intellectuals of the time, he did not see the War as a struggle for democracy, but believed it was just another opportunity for the imperial powers to redivide the world.

At War's end, Mills joined the Department of Sociology at Columbia University. At a time when academic protocol dictated that professors dress conservatively, in button-down shirt, necktie, and jacket, Mills dressed as a lumberjack – in flannel shirts, leather jacket, and work boots. He commuted to Columbia on his BMW motorcycle while carrying his books and papers in a duffel bag.

Mills developed an international reputation as he traveled extensively. In 1956, he obtained a Fulbright lectureship at the University of Copenhagen. Three years later, he was a visitor to the London School of Economics. In addition to journeying to countries on both sides of the Iron Curtain, Mills spent time in Brazil and Mexico and visited Cuba a few months after the triumph of that country's revolution.

Mills died of heart failure on 20 March 1962 at the age of 45 years. He was buried in Oak Hill Cemetery, Nyack, New York. On his headstone is inscribed the aphorism taken from the opening paragraphs of *The Marxists* (1962), his last book: "I have tried to be objective. I do not claim to be detached" (Summers, 2008: 9).

Major Works

The major works of C. Wright Mills may be subsumed under four general groupings. First, there is the book, *Character and Social Structure*, where he articulates the social psychological theoretical framework that informed many of his other writings. Second, there is the important trilogy on power and social stratification – consisting of *The New Men of Power*, *White Collar*, and *The Power Elite* – in which Mills critically discusses the American class system. Third, there are his polemical tracts – *The Causes of World War Three* and *Listen Yankee* – where he advocates for a politics of responsibility and truth. Finally, in his most famous book, *The Sociological Imagination*, Mills presents his vision of what sociology should be and what it has to offer. Throughout all of these writings, Mills had two main objectives that required that he consider the character of individuals in the context of their social structure: to define and dramatize the essential characteristics of his time, on the one hand, and to see various populations as actors in the social drama of the twentieth century, on the other.

The Sociology of Persons and the Psychology of Institutions

Character and Social Structure (1953), which Mills coauthored with Hans H. Gerth, is a concise and systematic statement concerning the psychological nature of five major institutional orders: (1) political, (2) economic, (3) military, (4) religious, and (5) kinship orders. Here, Gerth and Mills not only consider how types of personalities are anchored in each of the institutional orders but also discuss how the institutional orders form social structures. Their goal is to construct a working model of persons and society by combining the sociology of persons with the psychology of institutions. This synthesis produces for Gerth and Mills a 'social psychology' through which they aim to achieve three objectives. First, they attempt to describe and explain the conduct and motivations of people in various types of societies and at various points in time. Second, they ask how the external conduct and inner life of one individual interplay with those of others. Finally, they seek to describe the types of persons usually found in different societies and then to explain them by tracing their interrelations with their societies.

Gerth and Mills indicate how social structures shape the personalities of people as historical actors. In developing a social psychology that considers the objective social functions of institutional orders alongside the subjective meanings of institutional members, Gerth and Mills combine key concepts from the work of George Herbert Mead, Freud, Marx, and Max Weber. Simply put, in emphasizing the roles people play in various institutions, Gerth and Mills demonstrate how 'character structures' – personality traits and conduct patterns – are molded by the institutional orders to form historical types of social structures.

The Class Structure and Power System

The New Men of Power, *White Collar*, and *The Power Elite* constitute Mills's studies on the American class structure and power system. These books attempt to relate the psychological characteristics of certain groups and their individual members – labor leaders; white-collar workers; and the political directorate, the chief

executives of large corporations, and the warlords – to the stratified milieu of post-War America. Mills is chiefly concerned with power and the powerful: the elites, exploiters, and policy makers.

In *The New Men of Power* (1948), Mills focuses on the American labor movement and explains the rise of union leaders and their role as a new elite. The book is basically an analysis of the character of America's labor leadership – the positions they occupy, their career lines, and the traditions and anxieties that motivate them. Endeavoring to relate a type of social role to a particular social structure, Mills is interested in union leaders not as individuals but as a social type formed by the roles they played in a political economy that was changing from laissez-faire to monopoly and a state capitalism with many corporate features.

Given that the U.S. economy had, since the Great Depression, been racked by the cycle of slump and war and boom, Mills's concern was that post-War America was drifting toward a war-oriented economy drawn into the Cold War conflict with Soviet Russia. He believed that only the powerful force of labor unions as agencies of protest could stop the U.S. from an incessant spending of large sums on munitions and other military items. As members of a strategic vanguard and the only potentially liberating mass force, the leaders of American labor – the new men of power – along with the labor intellectuals (i.e., the union's lawyers, editors of the union's newspapers, economists, statisticians, and research directors) could form an alliance of power and intellect to combat the main drift that was transforming the U.S. into a corporate garrison state. Mills, however, had little confidence that the leaders of trade unions would broker any opposition to a militarized economy. They were too conservative politically and too inhibited intellectually to seek the egalitarian, democratic society. Instead, they desired only to stabilize their power and position. Seeking a larger cut of the economic pie, the labor leaders had become politically and economically absorbed into the new corporate–government complex and had relinquished any aspirations for seeking structural change. As such, there was little that ideologically distinguished them from those leaders in the political, corporate, and military spheres.

Today, unions in the U.S. are far fewer in number compared with when Mills wrote about them in the mid-1940s. Union membership dropped from just over 35% of all workers in 1945 to less than 12% in 2012 (The Foundry, 2013). In fact, union membership has declined to almost exactly the same percentage as it was in 1930, before President Franklin D. Roosevelt encouraged the growth of unions.

By the mid-1950s, Mills had become thoroughly disillusioned with labor's ability to participate in a political movement to transform American society and no longer saw union leaders as players in the higher circles of power. His disenchantment with the labor movement of the working class led him to turn his attention to the next rung in the stratification hierarchy: the white-collar workers of the new middle class.

In *White Collar* (1951), Mills explains that how certain structural and occupational changes taking place in mid-twentieth-century America were affecting the psychological character, the social biographies, and the social roles of white-collar workers. According to Mills, the increasing bureaucratization of U.S. society coupled with the centralization of corporate power gave rise to a world of big organizations inhabited by the 'new middle class,' or those white-collar workers involved primarily in sales and management and whose work situation was increasingly bureaucratized by the 'command hierarchies' of business and government. As dependent employees they planned, administered, recorded, distributed, and managed for others. The white-collar workers of the new middle class included salespeople, corporate managers, clerical workers, and bureaucratic professionals such as salesmen and public relations specialists, who were needed to manage, design, sell, and keep account of production. Their characteristic skills involved the handling of paper, money, and people. By the middle of the twentieth century, one-fourth of the labor force was made up of employees working in large bureaucratic corporations.

The white-collar employees had become professionalized occupants of specified offices and specialized tasks, working in impersonal bureaucracies that made their work dull and routine. This meant that they experienced feelings of frustration, despair, anxiety, and insecurity. They had become powerless and alienated because they could not realize themselves in their work, for work had become a set of skills sold to another. These transformations of power striped the white-collar professionals of any control over their work. And because there existed a separation between the product and the processes of work, they had never acquired a sense of craftsmanship – of purpose and fulfillment – from their jobs. For them, work had no intrinsic meaning and provided no gratification.

The white-collar managers, clerks, and bookkeepers were cogs in a business machinery that had routinized greed and made aggression an impersonal principle of organization. Mills asserts that the white-collar salaried professionals were forced to accept the meaninglessness of their working life. As a result of the alienating conditions of modern work, for the mass of employees work had a generally unpleasant quality.

Further, the more the middle classes experienced their life as one of powerlessness, the more apathetic they became to politics of any kind. They were neither radical nor liberal nor conservative nor reactionary; they were 'inactionary,' strangers to politics, and history was being made behind their backs. In short, middle-class white-collar workers had become 'cheerful robots,' a mass of confused and unfocused automatons adrift in a bureaucratic world not of their own making.

Elaborating on the issues of increased bureaucratization, the consolidation of power, and political indifference, Mills's *The Power Elite* (1956) is a study of stratification that reveals a tripartite ruling stratum in U.S. society. His basic thesis is that as the institutional means of decision, information, and power became more coordinated and as the public became more politically uninformed, there had arisen a national 'power elite' with tiers and ranges of wealth and power of which people in the rest of society know very little. Mills identifies the American power elite as that relatively inaccessible small group of individuals and families who possess disproportionately more money, power, and prestige, as well as all the experiences, privileges, and trainings, which these resources provide.

He sees the elite of power as occupying pivotal positions in the three major hierarchies and organizations of modern society at that time: the machinery of the state, the big

corporations, and the military establishment. Accordingly, as members of the political directorate, the corporate rich, and the high military, the power elite command the dominant institutions of a dominant nation, and are in a position to make decisions of enormous consequence for the underlying populations of the world and to determine the course of events. The general public, in its supreme disinterestedness, frequently does not know that these decisions are being made until well after the fact. In short, the power elite are people of power within the coordination of political, economic, and military decision.

The 'political elite' group consists of higher politicians and key government officials, but in particular the president, vice president, and the members of the cabinet. It also includes the White House staff as well as the most important appointed heads of major regulatory agencies and commissions. Aside from occupying the executive command posts of the political order and forming the political directorate, the political elite are also the legal, managerial, and financial members of the corporate elite.

The second group composing the triangle of power, the 'corporate elite,' is made up of persons who occupy the top command posts in the giant corporations. The corporate elite also includes top-level management, the major stockholders, and the corporate lawyers representing the largest financial and industrial corporations in the country. At the very top stratum are the high-ranking executives, the 'corporate rich,' who manage the corporate complexes and make the key economic decisions. As the corporate world became more intricately involved in the political order, these executives became intimately associated with the politicians, and especially with the key politicians who form the political directorate of the United States government. Additionally, as increasing numbers of corporation chieftains enter government directly, the result is the emergence of a new political economy at the apex of which are situated those who represent the corporate rich and the political elite.

Finally, the third sector of this ruling triumvirate is the 'military elite,' who oversee the largest and most expensive feature of the U.S. government, the military order. At the top of the military order's bureaucracy, just below the president and the secretary of defense, is the military board of directors, the Joint Chiefs of Staff. Immediately below the Joint Chiefs, there is a circle of generals and admirals presiding over the elaborate and dispersed military forces as well as the economic and political liaisons necessary to maintain those forces. Thus, alongside the corporation chieftains and the political directorate, the generals and admirals of the Pentagon have been given increased power to make and influence decisions of the gravest consequence.

The Joint Chiefs of Staff, along with the munitions contractors who supply them with weapons, comprised a new and potent force in making the key decisions regarding U.S. foreign policy and international relations. Indeed, the military and corporate elites became political insiders serving as the president's most influential advisors. Mills warns of a new corporatism – directed by the political, industrial, and military elites – that points at the trend toward a permanent military economy. A few years later, President Dwight D. Eisenhower, himself a member of the power elite, echoed Mills's concern in his farewell presidential address to the nation, cautioning the American people about the burgeoning 'military–industrial complex.'

By using the mass media, the power elite of the three interlocking and coordinated directorates – the machinery of the state, the big corporations, and the military establishment – are able to persuade the mass of people into believing that through the democratic process, they have made the key decisions, when in fact they have not. Rather, it is the power elite who determine the course of historical events.

The Politics of Responsibility and the Politics of Truth

Mills's stinging critiques of U.S. society, world affairs, and professional sociology will leave his readers with a deep sense of pessimism or else provoke them to organize, mobilize, and take action for change. This latter inspiration stems from his admonition to sociologists and other intellectuals that they must be motivated by a commitment to politics. Indeed, throughout his later, more polemical writings – *The Causes of World War Three* and *Listen Yankee* – he calls on scientists and artists, ministers and scholars to practice the 'politics of responsibility' (Mills, 1958) and assert moral leadership. This means that intellectuals have an obligation to hold those in power accountable for the decisions they make and that affect human destiny. And in the late 1950s, at the height of the Cold War between the U.S. and the USSR, there was no decision that would have more momentous, and calamitous, consequences for the whole of humanity than thermonuclear war.

The Causes of World War Three (1958) is an explicit evocation of the politics of responsibility. In it, Mills maintains that the power elites in the United States and the Soviet Union were leading the two nations to a total and absurd war. These two superpowers intimately shared the 'military metaphysic,' a way of thinking in which everything in the world situation is officially defined in terms of national security and defense. As such, Mills calls upon the clergy, scientists, and the intellectual community to take a responsible and moral stand on the issue of peace and nuclear disarmament. He also calls for a rational response and a commitment to the task of overcoming widespread civic apathy, indifference, and elite irresponsibility concerning the annihilation of the human species through nuclear war. Mills endeavors to persuade American and Soviet intellectuals to prevail over the organized irresponsibility and unrealistic decisions of their respective countries' power elites and to, by their own efforts, sue for a separate peace. Mills believed that only in this way could the drift and thrust toward World War III and mass destruction be reversed.

But more than being politically responsible, Mills also maintained that social scientists and other intellectuals hold a politically informed notion of truth. This was a 'politics of truth' (Mills, 1959) – the critical voice of the intellectual that exposed the truth about the political power relations in U.S. society. This meant that intellectuals are duty-bound to tell the truth – to disclose the facts – about social reality; particularly, since this reality was being distorted by the stultifying culture of mass society and the manipulation of the mass media. Thus, in *Listen Yankee: The Revolution in Cuba* (1960), Mills seeks

explicitly to present to the U.S. public 'the truth' about the recent Cuban Revolution.

Shortly after the triumph of the revolution, Mills visited Cuba in order to observe firsthand its accomplishments in transition. Given its absence from the news of Cuba in the US, his goal in this book was to clearly and emphatically present the 'voice' of the Cuban revolutionary to Americans. On his trek through the island, he witnessed the innovative ways in which the common people were beginning to construct an entirely new society. Mills also interviewed scores of Cubans, from all walks of life, who were close to events and who were eager to express their sentiments. After a couple of weeks on the island, he returned to the U.S. and began writing *Listen Yankee*.

The book consists of a brief introduction followed by eight 'letters' in which Mills uses direct speech to convey a composite viewpoint of how the Cuban revolutionaries see their revolution as well as how they define their aspirations and their relationship with the United States. He considers Cuba's voice as the voice of the hungry-nation bloc (that is, Asia, Africa, and Latin America), and the Cuban revolutionary, he believes, was speaking (mainly through his book) in the name of many people in that bloc. For Mills, it was imperative that Cuba's voice be heard in the United States. Up to that point, the American public had virtually ignored Cuba, and Mills pleads with them to hear well the message of the Cuban Revolution; for only by dealing with the perils of ignorance could the perils of disastrous mistakes be avoided.

One year after the publication of *Listen Yankee*, President Eisenhower approved the CIA-sponsored Bay of Pigs military invasion of Cuba to overthrow the left-wing government of Fidel Castro. The failed invasion increased Castro's popularity as Cuba's leader and likely led him to pursue closer ties with the Soviet Union. Castro remained leader of Cuba for the next 50 years and the island nation, located 90 miles south of the United States, is today one of the world's remaining socialist states.

The Sociological Imagination

The Causes of World War Three and *Listen Yankee* established Mills's image as a public intellectual. Between those two books he produced the one for which he is best known in academic sociology: *The Sociological Imagination* (1959). Part primer, part polemic, Mills wrote it for two main reasons: to inveigh against the current dominant 'schools' in academic sociology and to articulate his own version of sociology.

A trenchant critic of what he saw as the two major sociological orientations in the 1950s, Mills scorns, on the one hand, the narrow, technical procedures of researchers like Paul F. Lazarsfeld, and on the other, the grandiose conceptual perspectives of theorists like Talcott Parsons. According to Mills, researchers had become so obsessed with particular methods that they were unable to see, much less study, the bigger questions pertaining to the social forms and tendencies that directly affect people's lives. They were engaged in 'abstracted empiricism,' an approach that converts the pressing social issues of the day into mundane statistical assertions. And given that research technicians were overly focused on trifling and specialized topics such as public opinion and voting behavior, they ignored the larger issues of social structure such as those dealing with the legitimacy and use of the existing distribution of power. Today, abstracted empiricism is a pervasive component in sociology as evidenced by the multitude of quantitative and narrowly focused studies published in major journals such as the *American Sociological Review*. Indeed, it has become more popular with the increased use of high-speed computers, statistical analysis, and large-scale data sets that produce studies devoid of sociological meaning and that ignore or deny the existence of social structure.

Mills also attacks Parsons's 'grand theory' or his general conceptual scheme for analyzing the structure and processes of social systems, and accuses him of being so preoccupied with creating concepts that Parsons cannot define in a clear and orderly way the social problems at hand, much less guide efforts to solve them. Mills urges grand theorists to abandon their high levels of abstraction and to instead observe problems in their historical and structural contexts. While grand theorizing fell out of fashion in the U.S. during the 1960s, its use continues in the work of European sociologists like Norbert Elias, Jürgen Habermas, and Niklas Luhmann.

As an alternative to abstracted empiricism and grand theory, Mills proposes the strategy that he believed must inform the sociological enterprise, 'intellectual craftsmanship.' This is a reflective style of work that guides sociologists' professional activities as well as what they, as persons, observe and experience in their everyday lives. In other words, social scientists must learn to use their personal experience in their intellectual work (Treviño, 2013). This consideration of personal experience, of biography, is central to what Mills regards as the most needed quality of mind for intellectual workers: the sociological imagination.

The 'sociological imagination' is a way of thinking that provides people with the insight into the social conditions of their existence and an understanding of the causes of their feeling trapped and uneasy, alienated and powerless. Its practical task and its intellectual promise are to enable individuals to grasp history and biography and the relations between the two within society. For only by seeing the interconnection of biography, or the intensive study of personality in its social setting, and history, can people understand their own experience, gauge their own fate by locating themselves within their period, and know their own life chances by becoming aware of all individuals in similar circumstances. Consequently, in employing the sociological imagination, people must ask three basic questions: (1) What is the structure of this particular society as a whole? (2) Where does this society stand in human history? (3) What varieties of men and women now prevail in this society and in this period? The sociological imagination, therefore, enables people to understand themselves fully, and when properly used, it can free them to be involved in the rational making of history. But in order to be free, individuals have to make the connection between their 'personal troubles' of the immediate milieu and those 'public issues' at the level of historically located social structure. It is the duty of those who employ the sociological imagination to continually translate troubles into issues and issues into the terms of their human meaning for them. Individuals must be aware that the malaise and frustrations they experience in their inner lives are linked to those problems residing at the level of social structure.

In his 2004 presidential address to the American Sociological Association, Michael Burawoy (2005) extended Mills's notion of the sociological imagination to include active participation in civil society, what Burawoy calls 'public sociology.' For Burawoy, the sociologist must enter into an unmediated dialogue in certain pockets of civil society such as with neighborhood associations, with communities of faith, with labor movements, and with prisoners. The core activity of public sociology is the dialogue between sociologists and their publics, and its political role, as Mills had previously stated, involves the sociologist "talking to publics and at kings" (Burawoy, 2008: 372; see also Mills, 1959: 181).

Freedom and Reason

As an undergraduate student, Mills was introduced to the American pragmatist philosophers, who believed that reason could serve as a guide to freedom. This link between reason and freedom served as an instructive force throughout Mills's writings.

As Mills saw it, the two values of modern Western culture – freedom and reason – were being threatened in post-War America. It could no longer be assumed that increased rationality necessarily made for increased freedom. The extreme complexity of the current era coupled with the concentration of power and knowledge made it so that ordinary people often could no longer reason about the great structural forces that affected their lives.

In modern American society, most people's freedom, which, for Mills, involves their chance to reason about available choices and then have the opportunity to choose, is constrained by power relations. Those with the power to make the larger decisions of their society are freer than those without the power. Mills draws two conclusions about individuals in their relation to the power structure of American society. First, though all people are free, some, by virtue of their placement within the social structure, are more powerful and freer than others to shape human affairs. Second, and subsequently, history is made behind most people's backs.

While Mills accepts the pragmatist notion that reason plays a pivotal role in freeing individuals from the constraints of their social structure, he does not assume that this emancipation is an automatic process. He maintains that individuals must be willing and structurally positioned to acquire the reason – the capacity to formulate available choices in life – that freedom requires.

A true democratic freedom can be realized only when individuals become aware of, and want to do something about, the social forces that constrain their lives. More to the point, individuals, in order to secure their freedom, must have not only the power but the desire to make decisions concerning their own lives and their place in history. True freedom of action means engaging in free initiative for self-determination and accepting responsibility for choices made. In the end, Mills's main concern was to utilize sociologically informed reason in the pursuit of a more just and democratic society.

Abstract

Theory of Mind (ToM) is a term coined to describe people's effortless propensity to search for intentions behind actions. ToM research began with primates in 1978 and continues in humans to investigate both the developmental stages of skills involving the ability to understand other's mental states – infants (7 months old) compute other's beliefs – and its brain basis. Research on ToM has always overlapped with research on autism. Findings indicate that individuals with autism have a diminished cognitive awareness of their own and others' mental states, and their brain connectivity in a multicomponents network is disrupted in different areas.

A Multi-Faceted Concept

People have the pervasive tendency to explain their own and others' actions in terms of beliefs, desires, and goals. The attribution of mental states represents a useful social strategy to make sense of and predict people's behavior. The terms 'Theory of Mind' (ToM), 'mindreading' or 'mentalizing' have all been coined to describe people's effortless propensity to search for intentions behind actions.

One of the finest examples of the predictive usefulness of ToM attribution comes from the fictional character of Sherlock Holmes, the great mastermind of detection created by Sir Arthur Conan Doyle in the nineteenth century. In 'A scandal in Bohemia,' Sherlock Holmes has been instructed by his client to find a photograph that a lady has safely concealed in her house. Sherlock Holmes' cunning plan is to make the lady think that her living room is on fire by tossing in a smoke rocket and raising a fire alarm. What happens afterward is exactly what Sherlock Holmes had predicted: the lady's instinct is at once to rush to secure the photograph, which is the object she valued most, and by doing so she accidentally revealed to Sherlock Holmes, who was in the same room, the secret hiding place. The case is brilliantly solved by the detective thanks to his correct attribution of intentionality to his opponent.

Intentionality is, according to philosopher Frank Brentano and von (1970) the feature that sets the mental states completely apart from the physical states. Mental states hold the property of 'pointing' toward certain objects or states of affairs (*Intendere* in Latin means to aim), but these objects or states of affairs need not exist. Intentionality is the common feature of propositional attitudes, those cognitive states that are described in everyday language with the use of a 'that' clause (typically beliefs and desires, i.e., " I believe that ….").

An important aspect of propositional attitudes – beliefs and desires, as well as intentions, thoughts, doubts, remembrances – is that they may represent actual or possible states of affairs. The states of affairs upon which people's propositional attitudes are directed may actually attain in the real world, but equally they might not: beliefs are often false, desires can be frustrated, and hopes may be dashed. Hence, propositional attitudes are states that 'do not exist here and now': they are states that are about or directed upon a nonexistent state of affairs or objects that can be true or false, and even paradoxical (e.g., "John believes that drinking water is safe," and "he believes that drinking H_2O is poisonous").

The term 'intentionality' refers to all mental states; hence, all mental states are intentional. These include propositional attitudes (beliefs, desires), pretense, intentions, and emotional states. Their differences can be expressed in terms of their contents: beliefs, desires, and pretense 'point toward' a proposition; intentions or goals and aims point toward a future state of affairs; and emotional states point toward a state of affairs.

The ability to pretend or to understand pretense, according to Leslie (1987), is remarkably similar to the logical properties of intentional states. At 2 years of age, infants possess not only the ability to form primary representations, but also meta-representations. The former ability allows them to understand the world in an accurate, faithful, and literal way – transparent representations – whereas the latter ability allows them to understand states that are not necessarily existing and true – opaque representations – for example, the child is not confused but delighted when his/her mother is pretending to hold a telephone when she picks up a banana saying "Let's call Daddy!"

An important distinction is within propositional attitudes, namely, between desire and intention. The simplest form of intention implies an action, whereas desire implies always an attitude toward a proposition; for example, "Mary wishes that she goes to Mars," is different from "Mary intends to go to Mars." Indeed, if Mary intends to go to Mars, she has to set off and organize the interplanetary journey, whereas if she wishes to go to Mars, she can simply daydream about it. Obviously in our everyday language such a distinction is not easy to apply: the terms 'wanting' and 'trying' are used frequently and are more ambiguous. If Mary says: "I want to go to Mars," it is not clear whether she is just uttering a metaphor, or whether she will really try to go to Mars.

In our everyday descriptions of people and ourselves the use of different emotion terms are as frequent and useful as belief/desire terms. Nevertheless, the general category of 'emotion' includes very different psychological states such as sudden reaction responses to people or objects and introspective experiences. The difference between emotional states and propositional attitudes is that their intentional content is different: emotions are mental states that point directly toward

a state of affair, for example, "I am afraid of snakes" whereas beliefs and desires are attitudes toward propositional content, for example, "I believe that snakes could be dangerous."

To sum up, mental states attribution includes various types of mental states, all with different properties. From the very pragmatic view of social science research, it is important to underline that when a test is created with the purpose of investigating the ToM ability, it is tapping into a very complex cognitive ability which allows people to make inferences regarding different intentional contents. Whether different contents of mental states are reflected in a multifaceted cognitive organization is a matter for investigation.

The Nature of Theory of Mind

The processes that underlie the development of ToM are still a matter of a sometimes tortuous debate. The concept of mental states seems as abstract as the concept of the electron, and there seems to be as little and direct everyday evidence for the existence of beliefs and desires as there is for the existence of electrons. Historically, researchers are divided in those who advocate theory–theory, modularity theory and simulation–theory. The first view assumes that possession of ToM concepts depend upon possession of abstract knowledge (e.g., Gopnick and Wellman, 1992). The second view assumes that possession of abstract concepts depend upon a cognitive mechanism, rather than upon knowledge (e.g., Leslie 1987, 2000). The third view assumes that we understand other people's behavior by recreating the mental processes on ourselves; hence, perception of others' actions is coupled with own's action (e.g., Gallese and Goldman, 1998). Different variations of these explanations have been proposed over the last decades; however, recent views emerging from neuroimaging literature on ToM (e.g., Apperly, 2008) agree that these different explanations do not bear heuristic value any longer. Indeed, the recent marriage between psychology and neurobiology has provided much impetus for future research into the 'social brain' (Brothers, 1990), which includes both the system of ToM and a 'mirror system' (Rizzolatti et al., 1996). The former enables us to understand actions in terms of desires and beliefs and the latter enables us to understand other's goals and intentions and to empathize with their emotions by a mechanism of motor resonance (Frith and Frith, 2010). Most importantly, there is consensus that future research will be in the direction of investigating various triggering inputs for these systems with particular emphasis on the distinction between automatic versus deliberate social signals (Frith and Frith, 2012).

Origin of Theory of Mind Research

Research into ToM began with primates. The very term 'Theory of Mind' was coined by Premack and Woodruff (1978) who, in a pioneering paper, asked whether chimpanzees have the ability to infer mental states from others' behavior. The first nonlanguage-based ToM test was used with Sarah, an adult female chimpanzee. She was shown a series of videotaped events in which human actors were struggling to obtain inaccessible objects, and then asked to indicate how she thought the human actor would solve his problem. One of the scenes, for example, presented the actor in a cage similar to that of the chimpanzee's, struggling to get bananas that were hanging from the high ceiling. The animal then was presented with a pair of still photographs, one of which depicted the actor engaged in a behavior that constituted a practical solution to the impediment, for example, stepping onto a box.

Premack and Woodruff argued that Sarah's consistent choice of the correct photograph can be understood by assuming that the animal possesses ToM: she solves such problems by being able to attribute to the actor both an intention or purpose and knowledge. According to the authors, when the chimpanzee watches the videotapes showing the human actor jumping to reach the bananas attached to the ceiling, she assumes that the actor wants the bananas and he is struggling to reach them. She also assumes that the actor knows how to attain the bananas so that when she is required to indicate which photograph depicts the solution, she chooses correctly the picture of the actor stepping on the box. However, these results can also be explained with no reference to mental state representations.

In a commentary to Premack and Woodruff's study, philosopher Daniel Dennett (1978) argued that the evidence of the primate's correct choice may equally well be supported by "supposing that [it is] derived from either habits (of thought) or belief about other features of the world (e.g., experienced regularities in the behaviors of others)" (p. 569). Dennett pointed out three crucial requirements for an experiment to establish whether subjects attribute mental states to others or not: (1) the actor's anticipated behavior is a novel action, in the sense of not being habitual or often repeated in the given circumstances; (2) the subject's response consists of an action as much as possible from his natural repertoire, rather than a highly trained artificial response; and (3) the perceived dependence of the subject's response on the other person's action should also be natural and obvious.

The first requirement is fulfilled when the belief attributed to another person is false. Only in that case, will the individual be expected to act inappropriately to the novel circumstance, hence, in all likelihood, not the way the person has typically acted in the past. Correctly reporting someone's belief when it differs from your own cannot be done by simply referring to one's own knowledge of the facts. The other two requirements are fulfilled by communicative acts, such as asking a question or requesting something from the other individual.

Following Dennett's suggestions, Wimmer and Perner (1983) accepted the challenge to develop a test to investigate children's ability to attribute mental states to others. The classic 'False Belief Task' paradigm investigates the ability to understand that a belief is opaque, namely, that there can be different beliefs about a single event. Hence, the test is based on the assumption that understanding someone else's false belief requires the representation of a mental state that differs from what is known to be true. If a child is able to represent another's mental states, then he or she will be able to predict the ignorant person's behavior, which is no longer appropriate in the changed circumstances.

The original test, a *location change* task, was constructed by Wimmer and Perner around a story character, Maxi, who hides

a chocolate in a box before he goes out to play. While he is out, mother comes in and moves Maxi's chocolate from the box to the cupboard. Then Maxi comes in back from playing. The experimenter asks: "Where will Maxi look for his chocolate?" The test allows for distinguishing whether the child predicts Maxi's behavior on the basis of his own knowledge (Maxi will look where the chocolate really is) or whether he understands Maxi's false belief (Maxi will look where the chocolate was left). The child answers without the need of verbalizing his response, since a mere pointing gesture suffices. Results indicated that while most 4-year-olds correctly predicted Maxi's behavior on the basis of his false belief, most 3-year-olds answered on the basis of the new situation, without taking into account that Maxi's belief remained the same regardless of the reality changed.

In another False Belief Task, a *content change* task, the child himself is the holder of a belief which is revealed to be false. In the 'Smarties' task (Hogrefe et al., 1986) the child is asked to guess what a Smarties tube – well-known sweets' package – contains. After the child correctly answers "sweets" or "Smarties," the experimenter opens the package and shows the real content, a pencil. The lid is then replaced and the child is asked: "When you first saw this box, before we took off the lid, what did you think was inside?" (own mental state question). In this task 3-year-olds do not seem to recall their false belief but answer instead "a pencil." The same result occurs when the child is asked what another child would say when shown the same tube of Smarties (other person mental state question): 3-year-olds expect a true belief while 4-year-olds recognize the false belief (Perner et al., 1989; Wimmer and Hartl, 1991).

Finally, in 1985, Baron-Cohen, Leslie and Frith tested the hypothesis that children with autism, with a mental age above 4 years, fail to take into account other people's beliefs. They used a variation of the Wimmer and Perner (1983) paradigm with a group of normally developing children (mean age 4.6 years), a group of Down syndrome children (mean age 11 years), and children with autism (mean age 12 years). Children were presented with a scene with two dolls, 'Sally' and 'Ann': Sally has a basket and Ann has a box. Sally puts her marble in the basket and leaves the scene. While she is out, naughty Ann takes the marble out of the basket and puts it in her box. Question: Where will Sally look for her marble? The results showed that 80% of the children with autism failed, pointing to the location where the marble actually was, whereas the majority of both control groups passed (85% of the normal developing children and 86% of the Down syndrome children). This finding has been replicated in a number of studies, using the verb 'think' in the question rather than 'look' and real people rather than dolls (Leslie and Frith, 1988). Furthermore, Perner et al. (1989) replicated the findings from the 'Smarties' task with a control group of children with specific language impairment, so that the possibility that children with autism failed to understand false-belief tasks on the basis of a general language deficit was ruled out.

Research on ToM began with Premack and Woodruff's seminal paper asking whether chimpanzees have a ToM: on the 30th anniversary of its publication, Call and Tomasello (2008) reviewed all data available and concluded that chimpanzees do understand others in terms of a perception–goal psychology but do not seem to understand false beliefs in particular.

Theory of Mind and Own Mental States

In the Premack and Woodruff's paper, ToM was defined as follows: "In saying an individual has a ToM we mean that the individual imputes mental states to himself and to others […] The system can be used to make predictions, specifically about the behavior of other organisms" (p. 515). While the majority of research has focused on attributing mental states to others, attribution of mental states to self has been relatively neglected in the literature.

Everyday common sense is that we know what 'we think' better than what 'others think.' However, data from typical development give little evidence to date of better performance on task requiring reflection on own mental states and to others. The ability of self-reflection emerges no earlier in development (Wellman et al., 2001), and neuroimaging findings appear to suggest that regions active during attribution of own mental states overlap with region active during attribution of mental states to others (Happè, 2003).

The task used most widely to assess recognition of false belief *in self* and others is the 'Smarties' unexpected contents task described above. Indeed, participants are asked both a Self-False belief question – what they thought was inside the box before they looked – and an Other-person False belief question – what another person will think is inside the box before they look. On the Smarties task, individuals with autism tend to perform as poorly on the Self test question as they do on the Other-person test question (Baron-Cohen, 1991, 1992; Fisher et al., 2005; Russell and Hill, 2001). However, there is confound in this particular procedure because children could benefit from the request to state at the beginning of the test what they think is inside the Smarties box. They 'verbalize' their false belief before the critical questions are asked. This sort of 'memory for statement' could be the strategy that children use to pass the test questions without really reflecting on their own belief (Williams and Happè, 2009). Williams and Happè crucially manipulated the conditions of a content change task (the Plaster task) in a way so that the participants had to select a box where they thought there were plasters without being asked to explicitly verbalize their belief. The main finding was that participants with autism performed significantly less well on the Self test question than the Other-person test question on this new task. Other studies suggest that individuals with autism have a diminished awareness of their own and others' intentions and that this diminution is associated with other impairments in ToM (Williams and Happè, 2010).

The Developmental Shift between Three and Four Years of Age in and Autism

The issue of ToM deficit in autism became interconnected with the issue of the failure of 3-year-old children and the developmental shift in understanding false beliefs. Paradigms first introduced to explore ToM in normal children were also used with children with autism. In fact, it is crucial to understand the reason why both the groups fail the same task: could it be that young children are similar to children with autism at the cognitive level? The answer is

negative: extensive research has shown that 3-year-old normally developing children and older children with autism are very different from one other, even though both fail false-belief tasks.

The 'false photograph' paradigm (Leekam and Perner, 1991; Leslie and Thaiss, 1992) based on a task devised by Zaitchik (1990), nicely demonstrated that children with autism do not find difficulties with any 'out-of-date' representations, but only with those based on mental states. During the experiment, a Polaroid photo is taken of a scene, then placed face-down in front of the child while the scene is changed (e.g., an object is moved from the scene, or is swapped with another object). Children are then asked: "In the photo, where is the object?" Zaitchik's study showed that normally developing 3-year-old children find this task as difficult as standard false-belief tasks, whereas 5-year-olds find no difficulties in both tasks. Leslie and Thaiss (1992) demonstrated that all the children with autism with a verbal mental age ranging from 4.4 to 14.5 years passed the false photograph tests and the majority of them (77%) failed the false-belief tests. By contrast, normally developing children aged 4.5 years passed all tests. This finding has been replicated with analogous tasks, for example, using line drawings and maps, thus dismissing concerns that the children's inexperience with cameras might effect their response (Charman and Baron-Cohen, 1992, 1995; Leslie and Thaiss, 1992).

Another relevant study has shown that younger normally developing children not only fail 'out-of-date' mental state tests (e.g., false-belief tasks) but also 'out-of-date' non-mental states tests (e.g., 'screen task') that older children with autism are able to pass (Roth and Leslie, 1998). In the screen task children are first presented with a scene, then the objects are moved behind an opaque screen, and a new set of objects is placed in *front* of the child who watches a change of object location. The child is then asked to indicate the location of the object *behind* the screen. Both, children with autism older than 4 years and normal 3-year-old children, fail to represent mental states (false-belief task), however only the 3-year-olds fail to represent an out-of-date state of affairs (screen test).

The failure of 3-year-olds with either mentalizing tasks (false-belief), misrepresentation tasks (out-of-date photographs, drawings, maps) or executive control tasks (scenes hidden by a screen) all seem to reflect a performance limitation associated with executive functions not yet fully developed. By contrast, failure on false-belief tasks and success on all other tasks by children with autism reflect a selective impairment in understanding the mental states of others. Thus, children with autism show a competence limitation in mentalizing, rather than to executive functions processing problems.

Strong corroborative evidence comes from the subtle but effective manipulation of task instructions. Several investigators have modified the false-belief task so as to make it simpler – for instance, by making the question simpler, more specific and more pragmatically natural (e.g., Siegal and Beattie, 1991; Surian and Leslie, 1999). Surian and Leslie showed that 3.5-year-old normally developing children who failed the standard question "Where does Billy think the ball is" passed the modified question "Where is the *first* place Billy will look for his ball?" However, children with autism who performed at the level of the normal 3.5-year-old children on the 'think' question were not facilitated by the 'look first' question. According to the authors, the format of this question enables the prepotent response, which maintains that Billy has a true belief (as a default assumption), to be inhibited.

Developmental Time Course of Theory of Mind Skills

During the last decade developmental psychologists became very interested in investigating developmental ToM, namely, at what age children acquire the concept of belief.

Extended research showed that children younger than 4 years perform very poorly on several versions of the false-belief task (Wellman et al., 2001; Wellman and Liu, 2004; Milligan et al., 2007). Children's performance does not improve either if they are asked about where the puppet *will look* for the object, or where it *will say*, or *think*, or *know* that the object is (Wellman et al., 2001) or when children are requested to provide nonlinguistic answers (e.g., de Villiers and Pyers, 2002; de Villiers and de Villiers, 2000; Wellman et al., 1996).

However, these failures do not necessarily establish that younger children lack the ability to represent mental states of others. Toddlers at 2.7 years of age adjust their communicative behavior by taking into account whether their interlocutors have witnessed where an object has been hidden (O'Neill, 1996). Other evidence suggests that 3-year-olds have an implicit understanding of mental states (Garnham and Ruffman, 2001) or an understanding in which they have low confidence levels (Ruffman et al., 2001). When children aged 3 years are asked explicit test questions rather than standard ones, their performance improves (e.g., Siegal and Beattie, 1991; Surian and Leslie, 1999; Yazdi et al., 2006). Thus, there is evidence that children younger than 4 years do understand beliefs. Can infants represent mental states such as beliefs? Since infants cannot be tested with elicited-response false-belief tasks, recent investigations adopted spontaneous-response false-belief tasks in which infants' understanding of an actor's behavior to be guided by her true or false belief about an object hiding place is inferred by behavior they produce as they observe a scene unfold. In particular, the task measures infants' 'surprise,' that is, violation of expectation, indicated by longer looking times at an unexpected scene as opposed to an expected one. A study by Onishi and Baillargeon (2005) tested 15-month-olds and infants looked as the agent reached to the location where the agent falsely believed the object was hidden but looked longer when the agent reached to the other location where the toy was indeed hidden. An eye-tracking study by Southgate et al. (2007) demonstrated that 25-month-old infants correctly anticipate an actor's actions when these actions can be predicted only by attributing a false belief to the actor. Even infants, 13-months old, formed different expectations about a puppet's future behavior depending on whether the puppet had previously seen a desired object being put beyond a screen (Surian et al., 2007). A novel false-belief paradigm based on helping as an active behavioral response (Buttelmann, Carpenter and Tomasello

et al., 2005) showed that by infants, 18 months of age, successfully took into account the adult's belief in the process of attempting to determine his goal. Hence, a growing body of evidence strongly suggests that children before being able to pass elicited response false-belief tasks, have at least an implicit understanding of others' beliefs (Baillargeon et al., 2010; Csibra and Gergely, 2013; Leslie, 2005; Luo and Baillargeon, 2010; Luo, 2011). Interestingly, infants of 7 months of age, an age by which infants attribute goals and intentionality (Csibra, 2008) *automatically*, that is, *effortlessly*, compute other's beliefs and seem to maintain them in their minds even in the absence of the agent (Kovacs et al., 2010). Recently (Heyes, 2014) has argued to maintain a certain caution in interpreting results that infants appreciate that others have false beliefs. Indeed, she argues that many findings can be explained by the operation of domain-general processes and in terms of 'low-level novelty'. However, the adoption of different experimental strategies could advance our knowledge of developmental theory of mind.

Brain Basis and Theory of Mind

The authors of the infants' research findings often underline that infants compute 'implicitly,' 'effortlessly,' 'automatically,' or ' online' mental states. These results give support to the suggestion, which was postulated during the early years of research in ToM, of the existence of a specialized neurocognitive mechanism that was engaged when computing mental states and that was selectively impaired in individuals with autism (Leslie, 1987). From the philosophical perspective, the existence of a dedicated 'system' was also postulated. According to Dennett (1987) we are constantly bombarded with sensory inputs that alert our system to the presence of an agent, inputs that make us adopt the so-called 'intentional stance' toward that agent in order to understand and predict its behavior. In the last decade functional brain imaging studies have indeed attempted to identify brain pathways involved during mental states attribution, both in healthy individuals and in people with autism. A neuroimaging study in particular has examined brain activation during an online attribution of mental states to geometrical shapes moving silently on a white background (Castelli et al., 2000) as to avoid any language-based or familiarity confounds on the task. Indeed, the exposure to simple, nonverbal stimuli evoked in participants' mental state attribution by their kinetic properties alone. Over the past decade, a dedicated brain network for ToM has been confirmed by a series of brain imaging studies (Frith and Frith, 2003; Saxe et al., 2004). Most of these studies implicate activation in medial frontal and temporoparietal cortex (STS) and the temporal poles/amygdala complex. As expected, this system shows malfunction in autism (Castelli et al., 2002; see also Zilbovicius et al., 2006; Kana et al., 2009). The specific roles of the frontal and posterior components of the ToM network are still debated. However, recent studies on brain connectivity indicate that these cortical areas are connected during ToM processing, but are disrupted in the brain of individuals with autism (Just et al., 2013).

Mind–Body Dualism

Rom Harré, Georgetown University, Washington, DC, USA; and Linacre College, Oxford, UK

Abstract

'Suffering', 'remembering', 'weighing 55 kilos', 'being in the doorway' are among the properties that are routinely assigned to individual people. While mental processes, such as remembering and mental states, such as being in pain, are ascribed only to people and beings similar to them, weight and location are attributes of many kinds of things that are certainly not people. Should this distinction in kinds of attributes shape our efforts to study people by considering each person to be a composite of two distinct substances – a mind and a body? Rene Descartes' famous argument for substance dualism subsequently appeared in various versions but it has been the focus of searching criticisms. Several alternative proposals for organizing the study of the attributes of persons into a coherent body of knowledge have been proposed. These include materialism or physicalism, that there is only one relevant substance, material stuff; and various versions of personalism, that 'person' is the primitive core of all descriptions of human life, conceptually prior to both 'mind' and 'body'. Wittgenstein's strategy in the face of the rerunning of the mind–body debates over centuries was to suggest that *both* sides of the dichotomy that has shaped these debates should abandoned and new distinctions introduced.

Dualism of Substances

Centuries of effort to understand the nature and activities of human beings have acknowledged the radical distinction between the nature of mental attributes and processes in which people engage and the materiality of their bodies, including their brains. Many, perhaps every state of mind is correlated with some state of the body, while only some states of the body are correlated with states of mind. Until recently most attempts to give a coherent account of human nature in all its fullness have been based on the presumption that the distinction between mental states and states of the body reflects a distinction between the mind as an immaterial substance and the body as a material substance. Nouns typically refer to substances, enduring stuffs the role of which in lay and scientific discourses, is to be the substratum to which attributes are ascribed. Thus, the person is taken to be a doublet, one component of which is mental stuff and the other material stuff. According to the Cartesian tradition to be discussed in detail below the properties of mental stuff (mind) and the properties of body stuff (matter) are utterly different. Not only is a person a substantival doublet but also, in a way that was never satisfactorily explained, a unity of mind and matter.

Some dualists have supposed that though in life mind and body are intimately conjoined the mind as a substance could be detached from the matter of the body and continue to exist with nearly all of the mental attributes that it had as a component of a person. Others have supposed that mental stuff would perish along with the material stuff with which it was conjoined in the life of the individual person. Mind–body dualism does not, without some additional premises, entail the immortality of the soul.

Descartes' Proposal

Descartes exposition in the second and sixth of his *Meditations on First Philosophy* (Descartes, 1641, in Latin and 1647 in French) includes some important insights and led to several versions of the dualist account of human nature. The first step in Descartes' analysis is to establish at least one secure truth about his own nature in the midst of doubts about what he previously thought he knew for sure. The only thing he cannot doubt is that he is doubting, and so he is sure he must be a thinking thing. In the *Sixth Meditation* he considers the status of his knowledge of material things including his own body. In a frequently quoted passage he declares "Nature teaches me, by these sensations of pain, hunger, thirst and so on, that I am not merely present in my body as a sailor is present in a ship but that I am very closely joined and, as it were, intermingled with it, so that I and the body form a unit" (Descartes, [1656]1981). However, knowledge of the truth of experiences seemingly of things other than myself is a matter for the mind, so as to warn him of what is safe and what is harmful 'for the composite of which the mind is a part' (*loc. cit.*). The body as a material substance is divisible, but the mind as a mental substance has no parts, nor is it affected by every part of the brain. Only divisible entities could decay and perish. The indivisible soul must therefore be immortal.

The depth of his original doubts depended on his playing with the idea that there might be a malevolent god deceiving him – but God is not a deceiver. Descartes' sensory knowledge of the material things he perceives in his environment are for the most part for his own good.

The root idea of a dualism of substance derived from the distinctiveness of mental attributes from the material attributes of the body deeply influenced philosophical psychology and continues to do so. If mind and body were distinct substances with no properties in common how could there be an interaction between them. This interaction is displayed in perception, a process by which matter acts on mind. It is also displayed in deliberate action, a process in which mind acts on matter? How could one be sure another person was a conscious being with a mental life if my contacts with this person were limited to appearances in the material world? Descartes himself noted that what appeared to be the people in the street might turn out to be automata dressed as people. The problem of

mind–brain interaction and the problem of other minds are still with us.

Early Criticisms and Revisions of Cartesianism

Pierre Gassendi, one of the authors Descartes invited to offer objections to his proposals, pointed out how empty was the idea of a 'the mind as a thinking thing'. Using the criterion of the ability to form a clear and distinct idea of something as a guide to the nature of that thing Gassendi argued that declaring that he had a clear and distinct idea of the mind as a 'thinking thing' this tells us nothing about the nature of the mind so it cannot be a clear and distinct idea of the mind. "It is far from true that a man who sees clearly that the mind thinks therefore sees clearly the entire intimate nature of mind" (Gassendi, 'Logic'. In: Bush, C.B., 1972: p. 190).

Gassendi developed a more complex pattern of relationships between mental and material aspects of the person and the duality of substances. Not all cognitive processes were carried out in the immaterial mind, only those of high intellectual abstraction. For example, he suggested that classifying and other low level cognitive processes were 'mechanical' and occurred in the brain. In *Syntagmata* (Gassendi, 1971[1658]: p. 336) he describes the *soul* as more or less the form of the body, rather as Aristotle might have described it. "It is such that in the same man it not only gives life, feels and moves, but also understands, reasons, wonders, probes abstruse questions, speaks, laughs, makes laws, discovers skills, and so on." 'Thought' is 'separate' only by abstraction from 'matter', while 'mind' is separate from matter in fact, for example as God and as intelligence are actually separate from matter. The *immortal soul* was not an intimately interwoven component of the unified person, but a stand-alone purely intellectual correlate that changed in synchrony with changes in the human being.

A century later David Hartley proposed a kind of dualism of process. 'Vibrations' of the small particles in the nerves and brain were in correspondence with matching streams of ideas. In Proposition 11 of Book 1 (Hartley, 1749: p. 8) he wrote, "… whatever changes are made in this substance [the white medullary substance] corresponding changes are made in our ideas, and vice versa". By mid-eighteenth century Hartley had no need to argue for the mind–brain dualism realized as vibrations and idea, which is the taken for granted metaphysical foundation for his neuropsychology.

Recent Criticisms

The Cartesian version of mind–body dualism has been under attack since the time of its original proposal in the seventeenth century. The basis of the Cartesian route to substance dualism is the seeming radical diversity of the kinds of properties that can be ascribed to a human being as person. There are those that incorporate extension, and those that do not. The essence of matter is extension so there must be a material substance in which they inhere. The parallel analysis of thinking as an unextended attribute of something leads to the mind as an immaterial substance. If this categorization of personal properties is defective the Cartesian case for mind–body dualism is undermined.

An indirect criticism of the Cartesian argument involves attempts to support the claim that there is only one substance, which is neither material nor immaterial, but has both mental and material properties, and indeed some properties which require both kinds of concepts in their analysis. The person is the primitive unanalyzable concept of choice for philosophers, such as P.F. Strawson (1959) and psychologists such as William Stern, whose 'personalism' has been revived by Lamiell (2010).

In his *Individuals* (1959) P.F. Strawson argues for the primitive role of the concept of 'person', making the point that "the Cartesian error is just a special case of the more general error … of thinking of the designations or apparent designations of persons as *not* denoting precisely the same thing or entity for all kinds of predicates ascribed to the entity designated" (Strawson, 1959: p. 105). All P predicates 'imply the possession of consciousness on the part of that to which they are ascribed'. Importantly, Strawson includes 'going for a walk' which only the conscious embodied person can do, as well as 'being in pain' which only the embodied but conscious person can experience. So M or material predicates are also ascribed to the primitive being, the person. There is a dualism but it is of predicates not of substances. People are the subjects of both M and P predicates, though only of human beings and those like them can P predicates be ascribed.

There cannot be a mind–body problem if there is no real interaction between monads. Gottfried Leibniz 'solved' the problem of how the unfolding of each windowless monad, roughly a person's and brain and that person's mind, each as a collection of inferior with a supreme monad which though utterly distinct, seem to stand in causal relations one to another. Leibniz solution to the impossibility of such a relation is the idea that each monad reflects the state of all the other monads as if there had been a causal relation between them. By the principle of a divinely preestablished harmony between each and all of them they unfold in apparent synchrony. Leibniz declared that if we have a complete conception of a substance it will be "sufficient … for the deduction of all the predicates of which the substance is or may become the subject" (Leibniz, 1987[1686]: p. 13, Section VIII). So all the thoughts and feelings of a mind will appear in due order without the intervention of causal influences from the rest of monads that constitute the human being and the 'surrounding' universe.

Dualism of Domains

Public and Private Cognition

During the twentieth century attention to the means by which cognitive processes were performed led to a realization that thinking could be carried out by group of people in conversation. Remembering as reminiscing and deciding as negotiating are cognitive processes that occur interpersonally. There was a new conception of dualism to take account of, that between public-social cognition and private-individual cognition. Public-social cognition is enacted in the material world, but is relevant to psychology only in so far as material entities, such as verbal utterances, are endowed with meaning. Private-individual cognition is enacted subjectively, but is relevant to human life only in so far as the meaning of privately

formulations of thoughts depend on spatiotemporal location of the embodied being. On this view, human bodies are sites for persons – which may be occupied but may be deserted. If the responsible people become convinced that there is no chance that human, that is meaningful activities, can be recovered from a human being in a vegetative state, that is there is no longer a person there, the life support can be terminated (Grattan, 2003: pp. 113–145).

Lev Vygotsky (1978) made this distinction the basis of his developmental psychology. An infant enters a world of conversations and meaningful actions, then, coached by family members, it acquires bit by bit the necessary skills for public–social interactions, gradually privatizing them and so acquiring a 'mind', which is in effect a repertoire of skills and effective practices. As the basis for cognitive psychology it points toward the realization that many cognitive processes have public-collective realizations and private-individual realizations. Some are realized only in the public-collective domain among people and others only in the private-individual domain, within oneself.

Recent Proposals of Alternative Distinctions

In a bold attempt to break the chain of endless debates around Cartesian impasses distinction, Wittgenstein (1953: §281) suggests that we should abandon the mind–body distinction that underpins them. The problems of how the states of a material substance can affect an immaterial substance (perception) and how the state of an immaterial substance can affect a material substance (deliberate action) are insoluble not because they are very difficult but because the terms in which they have been posed are the source of the intractability of all such problems. Not only should the distinction be abandoned but also with it both alternatives. Ceasing to think of human thought and action in mentalistic, immaterial terms, should not be followed by attempts to achieve satisfactory understandings of human thought and action in material terms. We should adopt some other nontoxic dualisms – for example, alive–dead, morally protected – morally vulnerable, and so on. We will examine several possibilities for this strategy for giving an acceptable account of the obvious fact of mental–physical dualism of processes and functions without requiring a foundation in the dualism of substances that has been the basis of attempts to link mental processes with the correlated physical processes that occur in every human being and in the members of other species capable of cognition.

However, a certain naive version of materialism that runs counter to Wittgenstein's proposal has appeared in 'neuropsychology'. The problem of how mental activities are related to neural activities is sidelined by using mentalistic predicates to refer to processes in organs of the brain – thus 'the hippocampus remembers' or the 'frontal lobes reason'. Bennett and Hacker (2003) have shown how this way of bypassing the Cartesian problem commits a 'mereological fallacy'. It is a fallacy to use a predicate of a part of an entity that gets its meaning as it is ascribed to the whole entity. Only persons can remember. This is not a matter of fact but a feature of the semantics of 'remembering'. Discoveries of the role of the hippocampus in the process of remembering make no difference to the primary way in which 'remembering' gets its meaning.

Hybrid Psychology

Following the implicit advice offered by Wittgenstein and turning to the Vygotskian framework of cultural-historical-instrumental psychology for significant dichotomies, suggests a very different distinction – that between tasks and the tools needed to carry them out. Tasks, such as playing tennis, mowing the lawn, and solving crossword puzzles, are defined culturally. The tools needed to carry them out, including, tennis racquets, lawn mowers, and brains, are defined materially. There is a strong conceptual link between tools and tasks in that while tennis racquets could be used as snow shoes their role as tennis racquets shapes their material attributes and depends on the cultural process they are adapted to. The same principle holds good for organs of the brain, such as the auditory cortex, which is adapted biologically to differentiating harmonic intervals, but has recently been readapted in each listener to hear the cultural artifact, the equi-tempered scale, as perfectly harmonious. As a general rule the criteria for identity of specific brain organs are derived from the function they play in cultural instrumental activities. We can identify the hippocampus as the site of certain memory processes because we already know what remembering is as a cultural instrumental phenomenon.

Supervenience

The well-established idea of emergent properties is based on a distinction between a base level domain of entities, which can be arranged in such a way that the composite so formed has at least some properties different from those of any of the entities that make it up. The distinctive higher level properties are said to be 'emergent'. For human beings, the base level properties are material, the constituents of 'body', while the higher level properties are mental, constituents of 'mind'. In some contemporary approaches to psychology they are said to be 'discursive', that is to consist of meanings that are ordered by reference to norms, conventions and story lines (Harré and Moghaddam, 2012). If it turns out that some body and brain states and processes could exist without there being associated mental states and processes but no mental states and processes could exist without there being associated body and brain states, *and* all differences in the one are correlated with differences in the other, the former are said to *supervene* on the latter. The relation between the two groups of states and processes is *supervenience*. If mental properties supervene on material properties then there cannot be a difference in mental properties unless there is a difference in material properties. I change from thinking about apples to thinking about pears, and at the same time (more or less) there is a change from one brain state to another. Or to put the matter otherwise "there cannot be two events alike in all physical respects but differing in some mental respect" (Davidson, 1980: p. 214).

Philosophical studies of supervenience involve many sided attempts to identify a relationship that takes account of the fact that the concepts that appear in the discursive practices of thinking and acting are manifestly distinct from those that are used to describe processes in the body while undermining the

possibility that the states and processes to which they refer inhere in distinct substances (McLaughlin and Bennett, 2011).

For 'weak' supervenience there is some material state for every mental state, fulfilling the 'differences' criterion. For 'strong' supervenience the same type of material state is correlated with each type of mental state. Weak supervenience of mind on body may be true weakening the two substances dualism. Nevertheless even to formulate the supervenience thesis independent criteria of identity of elementary items in each level domain may be required. There may be no explanation for the fact that research can demonstrate that there is some material correlated with each mental state or process. Only if we accept strong supervenience is the existence of a supervenience relation a ground for physicalism, the doctrine that there are only material substances and their states. Even then how entities, states, and process in the two domains are related remains unexplained.

Turing's Dualism

The advent of machine computation and the successful mimicking of some mental processes, at least as concerns input and output, by computing machines have suggested another take on the doctrine of mind–body dualism.

Impressed by the possibilities he saw in the construction and possible modes of operation of computing machines Alan Turing (1950) proposed a way of thinking about human cognition that can be condensed into a pair of analogies.

Thinking–Brain: Computing–Computer

To explore this scheme two analogies would need to be followed through. The first explores the brain–computer analogy. How like is a computer when programed to carry out an activity similar to the human brain when a person has learned some mental skill? The second explores the thinking–computing analogy. How like is machine computation to the human practices of thinking? Here we have another version of mind–brain dualism but which requires only one substance, the matter of the computing machine and its physical layout of registers, serial busses, etc.

This pair of analogies has been famously and controversially contested by John Searle (1980). In essence Searle's argument depends on the distinction between the physical tokens with which machine computation is carried on, and the meanings these must have if they are to play a part in human thought and action. There is a duality of meaningful entities and meaningless ones, but the duality is not between substances. It is between meaningless material entities as bits of stuff and material entities as symbols, entities that are meaningful to the members of a certain culture.

Conclusions

In the seventeenth century few doubted the immortality of the soul. The material body soon decayed. The key psychological attributes of the person such as memory could not decay if the soul of a particular human individual, his or her active intellectual, rational part, were to survive the dissolution of the body. They must therefore be attributes of something that is indissoluble, namely an immaterial component, the soul. It follows that a human being is a union of body and soul, of two substances. For this argument to work the attributes of each must be distinct from those of the other. And now the insoluble problems that bedevil the many attempts to make mind–brain dualism the basis of psychology appear. Resisting the temptation to presume that every noun must refer to something substantive many philosophers and psychologists have dropped 'the mind' and persisted with the monism of physicalism. Mental states and processes are declared to be nothing more than material states and processes (Churchland, 1984). This Procrustean bed so distorts the criteria for identifying cognitive, emotional, and intentional states of a person that it has seemed to many to be quite inadequate as the basis for a way to understand human life.

Persons might be singularities in a material social environment, to each of which we assign both mental and material attributes the meanings of many of which require both material and mental criteria. Moreover, there may be many distinctions other than the substantival, which could prove useful for understanding human life and the relations between the items in the broad spectrum of attributes that characterize a person.

Mindfulness

Abstract

In recent years, the concept of mindfulness has figured prominently in the development of innovative psychological interventions for physical and mental health. Mindfulness-based interventions have been shown to reduce recurrence of depression, stress, chronic pain, anxiety, and disordered eating, as well as to improve concentration and productivity. Mindfulness practices encourage participants to recognize automatic thought and behavior patterns and in doing so permit a more choiceful manner of responding to, and exploring, experience. The opportunity to relate to symptoms in this way may lead to significant shifts in both behavioral and physiological measures, ultimately leading to health improvements.

Mindfulness is a multifaceted concept that is often defined as paying purposeful attention to the present moment with a compassionate and nonjudgmental attitude toward one's experience (Kabat-Zinn, 2003/2013). Mindfulness is a kind of meta-awareness, an approach to consciousness, a skill, and a tool that can be used to observe thoughts and sensations of the body as they unfold. For example, when eating, one can focus directly on the richness of the flavors and the unique textures of the food while chewing, or instead they can attend to the highway while driving as they eat 'on the go.' In this second case, the experience of the food is not the focus of attention, although the individual may be aware to some degree that he is eating. Here, attention is divided between tasks. Mindfulness occurs in the first condition – when full attention and awareness are focused on the present moment, but this can extend broadly to all thoughts, perceptions, and experiences.

Mindfulness is the capacity of awareness that can be focused on inner and outer experiences as they are moment by moment. Mindfulness emphasizes self-compassion and acceptance so that the experiences one has, automatic or mindful, are not attached to in order to promote a renewed and present-centered approach. When not being mindful, individuals will carry out behaviors without direct awareness, or get lost in automatic thoughts that take them away from focusing on the immediate present. While the automatic processes of the mind are effective task managers, freeing up resources to plan and execute, they can also have negative consequences for health when they cause one to neglect immediate needs or to engage with the environment in suboptimal ways.

Mindfulness meditation has been the foundation of Buddhist practices for centuries but it is also considered to be an inherent human capacity. Mindfulness is not necessarily some enlightened experience only attained by those who practice, but it is also the occasioned attentional stance that occurs when one becomes conscious of thoughts, emotional states, or body sensations. Everyone has mindful moments, but some individuals are more naturally disposed to, or practice, being mindful and this may have consequences for health and well-being. Individuals who score higher on measures of mindfulness – who are more in tune with their inner and outer experiences – report greater levels of self-esteem, positive affectivity, optimism, self-actualization, autonomy, competence (Brown and Ryan, 2003), conscientiousness, agreeableness, self-compassion (Giluk, 2009), life satisfaction, and emotional intelligence (Baer et al., 2006; Brown and Ryan, 2003). Mindfulness has also been inversely associated with depression and anxiety, avoidance coping, negative affect, rumination, self-consciousness, anger, difficulties with self and emotion regulation, and neuroticism (Baer et al., 2006).

In recent years, there has been an explosion of research into mindfulness-based interventions (MBIs) for psychological and physiological illnesses (Grossman et al., 2004). These intensive 8-week programs have been shown to reduce depressive relapse, pain, anxiety, sleep disturbance, headache, and improve quality of life in both clinical and nonclinical samples (e.g., Keng et al., 2011; Hofmann et al., 2010; Chiesa and Serretti, 2009). Neuroimaging work by Farb et al. (2007) has shown that participants who complete an 8-week mindfulness course exhibit reduced activation in brain regions associated with narrative, or future thinking, and increases in brain region activity associated with present experiential thinking patterns, whereas wait-listed controls do not. This suggests that mindfulness practices have the potential to support fundamental shifts in the way we relate to information, allowing participants to adopt different modes of processing in a relatively short period of time. These transformations in neural activity may result in mindfulness developing into a more stable individual trait (Chiesa et al., 2010). Although the research is still in its infancy, these are some promising findings in the field of health.

Automaticity: To Do or Not to Do

Over the past hundreds of thousands of years, humans have benefitted from evolution's blind adaptations in many ways, including our unrivaled intellect. It seems, however, that the environment we have more recently shaped has some unintended consequences for our minds. While the more ancient problem-solving or 'doing' mode of processing was well suited for hunting, gathering, and living in small groups, it is called upon all too often in modern civilization and can run us into exhaustion. Today, life is no longer about what is directly in front of us – about direct conflict and resolution (e.g., run away from the tiger, chase the deer, make a fire, etc.) – but instead we

are able to consider past and future things like tomorrow's conference meeting, retirement, tuition payments, the dinner party on the weekend, or the health of family. In today's climate, there is much 'to do' and, for better or for worse, we possess a mode for just that. As such, the automatic doing mode is turned on constantly to help us 'get things done'; or so we think.

The automatic processes that dominate behavior and thoughts in *mindless* states can ultimately guide day-to-day functions without awareness or consideration. Everyone experiences mindless moments, perhaps arriving at a destination without remembering the drive, or sending a 'quick' e-mail only to spend an hour responding to messages or getting distracted on the Internet. We are so easily called upon to engage with our surroundings and while this 'doing' mode can be a very effective resource manager, it can also tap into and overextend resources in unnecessary and sometimes stressful ways without really seeking permission to do so. These processes disrupt the connection to the present by taking the mind to distant places past or future (i.e., temporal expansion), or by prioritizing endless preoccupations and to-do lists over immediate reality. Thoughts that occur sporadically in the mind can take over and reduce the ability to focus, flip one's mood, or cause one to overthink the small things. There are, however, other ways to operate. We do not have to be a slave to the busy 'doing' mode of the mind, and it is on this dimension that mindfulness works to reawaken individuals to a more purposeful perspective.

Mindfulness teaches participants to adopt a different mode, the 'being' mode, which allows individuals to observe things as they are instead of automatically engaging with their surroundings or thoughts. This shift presents a different way of sampling the environment, and a perspective that allows one to assess situations before mindlessly responding. In adopting this kind of practice, when an individual sees a long series of new e-mails in his inbox, he can prevent himself from immediately responding and ask whether now is a good time or not. Similarly, when one starts to ruminate about an embarrassing moment on the weekend, she can catch herself and bring her attention back to what is immediately present. Mindfulness practices teach participants to move beyond the wall of thoughts that flood the mind, and the response patterns that possess the body, to be more active passengers in their lives. Evidently, this may have substantial consequences for health.

Mechanisms of Mindfulness and Relapse Prevention in Mental Health

While even the most healthy of individuals are subject to the automatic thralls of the mind, the doing mode can become especially problematic to those with depression and anxiety disorders. This is in part because automatic and habitual negative thinking patterns dominate their headspace. Segal et al. (1995/2013) refer to the nonadaptive form of the doing mode as the driven-doing mode. In this mode, there is no immediate action or resolution to be taken; like a train without breaks, there is no stopping it from speeding along the tracks until it derails. While the doing mode, although often automatic, actually works on resolving real discrepancies (e.g., e-mailing, washing the dishes, shopping, and doing the laundry), the driven-doing mode strives to answer questions or decipher issues that have no apparent or immediate answers. Rumination is a central characteristic of depression as individuals spiral into endless questions, asking themselves: why do I feel this way, what is wrong with me, why can't I function normally; all with the hope of finding some resolution. In running these endless scripts, the driven-doing mode exacerbates negative moods caused by depression by magnifying perceived inadequacies, reinforcing them, but then leaving the individual with no answers or solutions. Depression and the driven-doing mode, manifested in rumination, take the victim captive in these counterproductive inner monologues filled with expectations of how one 'should' be or how they were in the past in contrast to how they currently perceive themselves.

In developing a maintenance program for depression remission, Segal et al. (1995/2013) recognized that teaching participants how to identify the automatic nature of thoughts, and the cascade of negative emotions that follow, would be helpful in preventing them from allowing these negative thoughts to run their course to eventual relapse. Depressive relapse occurs among 75–90% of patients, even after successful treatment (Kessler et al., 2005). After recovering from a major depressive episode, patients are left vulnerable to relapse because whenever negative thoughts and experiences occur, they can quickly reactivate depressive thinking patterns that become more and more hardwired with each episode. As such, it is very difficult to overcome ruminative habits, and individuals who revert to dysfunctional thinking patterns show increased cognitive reactivity to sadness provocation and are at the highest risk of relapse (Fresco et al., 2007). As a result, cognitive reactivity is a central target of mindfulness-based cognitive therapy (MBCT) (Segal et al., 1995/2013). MBCT, adapted from the earlier work of Jon Kabat-Zinn, was designed to teach participants to recognize negative and automatic thought patterns and has been shown to reduce responses that would typically agitate vulnerable individuals (Kuyken et al., 2010).

Research has found that MBCT is effective in reducing relapse (Teasdale et al., 1995; Bondolfi et al., 2010), cognitive reactivity (Kuyken et al., 2010), rumination (Williams, 2008), and worry (Evans et al., 2008) in depressed patients. MBCT changes the way in which participants relate to their thoughts by bringing their attention to the present while reserving judgment and reaction to the thoughts that naturally arise in the mind. In shifting to the 'being' mode, participants can in some way suspend negative thoughts in awareness before deciding how and whether to respond to them. Mindfulness interventions encourage decentering and hope to alter the way in which thoughts are perceived; instead of trying to manipulate or change negative thoughts and habits in participants who suffer from depression, mindfulness practices teach participants to attend to their thoughts and feelings promoting an understanding that such thought patterns are natural occurrences, not facts that reflect who they are. "By observing the activity of the mind, in the moment, in a spirit of inquiry rather than judgment, and by repeatedly decentering from old mental routines, questioning and testing them, patients learn to experience thoughts as events in the mind, rather than 'the truth' or 'me'" (p. 140) (Fennell and Segal, 2011). This releases

patients from the captivity of their thoughts because they can separate themselves from the judgments that routinely occur allowing them to evaluate their validity or reset their perspective. When a thought or idea enters the mind, participants are encouraged to nonjudgmentally observe or label those percepts as simply a 'thought,' 'emotion,' etc., before bringing their attention back to the breath. This practice allows individuals to shift their thinking from a self-oriented judgmental perspective to more broadly evaluate mental processes. Instead of thinking 'I am a terrible person,' they come to recognize that instance as merely a thought, not a true reflection of themselves.

Another mechanism of the preventative success of MBCT could be due to an increase in positive affect during remission (Wichers et al., 2010). Importantly, moment-to-moment positive affect and pleasure in daily activities has been shown to increase resiliency – an individual's ability to respond positively to life events. To assess this, a group of participants who had experienced at least one prior episode of major depression completed experience sampling post-MBCT intervention over a 6-day period (Geschwind et al., 2011). In experience sampling, participants are alerted at random times throughout the day and week to report on their current mood in their daily environment. Results showed that participants experienced boosted positive affect, well-being, and reward compared to a wait-listed control group, even when reductions in depressive symptoms were controlled for. It has been proposed that the shift in outlook of simple day-to-day interactions, perhaps walking to the bus, getting a coffee, or doing the dishes, may conjure up a more connected state and greater well-being (Kozasa et al., 2012; Bondolfi et al., 2010).

Mindfulness and Physical Health

Mindfulness-based stress reduction (MBSR) was first developed by Dr Jon Kabat-Zinn at the Stress Reduction Clinic at the University of Massachusetts Medical School (now at The Center for Mindfulness) in 1979. Before the application of mindfulness interventions to psychological disorders, MBSR was used to treat patients that suffered from chronic pain, and has since been applied to other physiological conditions ranging from fibromyalgia, to headache, to lower back pain (e.g., Morone et al., 2008). All of these conditions are extremely burdensome to patients, families, support systems, and employers because they are relentless and difficult to alleviate, often leaving the patient frustrated, depressed, and unemployed. When participants are enrolled in an 8-week mindfulness course, however, chronic pain has been found to significantly decrease. Kabat-Zinn (1982) proposed that this occurs by reducing participants' tendencies to catastrophize. Catastrophizing occurs when individuals negatively evaluate their situation, placing a great deal of weight on their circumstances, allowing them to balloon into something hopeless and unmanageable, as if blocking all light from the sun. Catastrophizing has been found to account for a large percentage of variance in participants' reports of pain severity as individuals who magnify and focus on their dire state experience more pain than individuals who are naturally more present focused (Schütze et al., 2010). The act of catastrophizing requires that the individual assess, judge, and expand on the negative aspects of their experience, all of which mindfulness addresses in opposition by helping participants recognize these patterns and change their natural response, highlighting its effectiveness in this population.

In Kabat-Zinn's original work (1982), he discusses that pain is an often-cited topic in meditative writings as practitioners are required to sit for extended periods of time. This can place a great deal of strain on the limbs of the body. When pain sensations occur during a sitting practice, meditators are encouraged to focus on the sensation fully and nonjudgmentally, resisting the urge to escape the ache. They are instructed to explore and accept such sensations and to appreciate them as transient and nonthreatening. In teaching this technique to chronic pain patients, this can alter their relationship with pain; by attending to sensations of pain nonjudgmentally – by acknowledging these events, but not avoiding the sensation – participants begin to recognize that the course of pain is not destructive and all-encompassing. In doing so, they become desensitized and less emotionally reactive to their experience of agony, whether or not there is any real reduction in the pain stimulus.

While this shift in attentional focus may contribute to the reduction of pain reported by chronic pain patients, acceptance-based interventions, like MBIs, have also been shown to increase pain tolerance. Indeed, when pain tolerance was measured in experienced meditators compared to non-mediators, the meditators required significantly higher heat levels in order to report the same degree of pain as non-meditators (Grant and Rainville, 2009). Even more, when a painful stimulus was applied to novice participants who completed only 20 min of mindfulness meditation for three consecutive days prior to testing, pain sensitivity also decreased compared to those who did not engage in meditation training (Zeidan et al., 2010). The authors found this short intervention to have similar effects on pain tolerance as doing simple math equations, which they suggest highlights that the focus and attention required during mindfulness meditation may play a role in its analgesic properties. In meditative practices, focusing on the breath or shifting attention could serve as a mental distraction, diverting thoughts away from negative stimuli and preventing catastrophizing of those sensations. With accumulated practice, these effects may be magnified as one's ability to cultivate a significantly heightened state of awareness improves.

Mindfulness-Based Interventions: A Unique Approach to Health

Mindfulness-based therapies bridge a very wide expanse between eastern and western medicine, bringing together techniques from ancient Buddhist philosophy and current clinical science. Over the past three decades, MBIs, like MBSR and MBCT, have garnered attention for treating symptoms of poor health. The programs are typically taught in group classes over an 8-week period with one class each week, a day of silence in week six, home practice 45 each day, and follow-up over 6 months postintervention. During MBIs, participants are asked to maintain their attention by, for example, focusing on their breath or conducting body scans. When participants

notice that their attention has diverted to other thoughts, they are instructed to recognize those diversions nonjudgmentally and return their attention back to their breath or body. This technique is taught as a tool that can be applied to daily life. When one realizes the occurrence of negative thoughts, the individual can acknowledge those feelings and 'let go' of their attachment and resulting emotional arousal in order to refocus attention on the present and respond differently. Mindfulness aims to cultivate nonjudgmental attitudes about the past, present, or future, to reduce automatic and potentially negative rumination about one's experiences and maintain openness toward one's thoughts. Both MBSR and MBCT are efficacious treatment programs that have been found to reduce recurrence of depression, stress, improve concentration and productivity, as well as alleviate chronic pain, anxiety, and disordered eating (e.g., Keng et al., 2011; Hofmann et al., 2010).

One of the key elements of MBIs is that unlike more standard methods of health care, these courses take a non-goal-oriented approach to treatment outcome. This can seem at odds with the current approach taken by medical professionals today. In Western medicine, we have come to think of treatment as having some end goal of health, cure, or symptom relief. As Fennell and Segal (2011) discuss, "[there appears to be] something of a paradox here. In the field of healthcare at least, people undoubtedly come to classes because they are suffering and hope for relief—and presumably therapists/instructors would not provide classes unless they believed this was possible" (p. 133). However, MBIs discourage instructors from trying to directly 'fix things' and participants from attaching to their end goals or hopes in taking the course. While MBIs do hope to alleviate suffering, they do not emphasize or invite this in as part of the process. With the aim of remaining open to experience, instructors emphasize that there is no correct way to do the practices and no ultimate state to achieve. Participants are reminded to be open to the process, and not to focus on the outcome, cling to, or hold expectations of themselves, but to just let things be as they are.

In clinical psychology, this is in sharp contrast to cognitive behavioral therapy, which focuses on eliminating suffering by asking participants to actively define their goals and the steps needed to attain them. In the case of MBIs, however, while relief from suffering underlies the intervention, the course promotes a light-hearted, open, and unfiltered approach to participants' experiences, with an emphasis to leave expectations at the door. The constant assessment of goals and attempts to 'succeed' can become problematic to the process by activating the nasty driven-doing mode of thinking: "am I doing this correctly?," "this isn't doing anything," "am I feeling better?," "Why can't I stop mind wandering?" Here, the participant starts to analyze his progress and gives in to the driven-doing mode. However, by identifying and disengaging from those thoughts when they arise, he can instead return to the present and permit the practice to run its course granting him the opportunity to explore experiences further and reinforce present state awareness.

The group setting of MBIs encourages open explorations of mindfulness practices because there are organic discussions during each class. The group framework is another important feature of MBIs for two reasons. First, it can be offered to more individuals than one-on-one therapy, with significant impact over a short period of time. Second, it encourages participants to recognize that many of the difficulties they face both generally and specifically, with regard to the course, are not unique to them but are shared by both their classmates and all humans to some extent. Interaction with the instructor during weekly meetings allows participants to listen and relate to the struggles that other group members experience. Through this dialogue, they recognize the tendencies to want to assess their progress and are reminded how to shift their state of inquiry to an open and curious one.

Mindfulness Practices and Stress Management

Stress is a part of each and every day, existing as dynamic tension in life. Without it, we would not adapt to perturbations in our environment. Stressors are environmental stimuli that force the body into reaction, or out of homeostasis. There is no zero level of stress, nor should there be, as stress is a force of existence much like gravity. Without stress, we would not learn, adapt, and grow. There is, however, a balance to be found as too much stress, or *distress*, is detrimental. Given the inevitability of stress, there are two important approaches to stress: stress reduction and stress management, in both of which mindfulness can play an important role.

Distress, or chronic stress, can cause serious health problems by overloading the sympathetic and neuroendocrine system, wearing down the immune system, increasing inflammation and oxidative damage, leaving individuals very vulnerable both emotionally and physically. While removing any sources of stress is undoubtedly beneficial to health, mindfulness interventions work to reduce and manage the stress that is unavoidable by both helping to identify stressors that are often undetected, and also by changing the way in which individuals respond and relate to stress. As discussed above, there is great value in being able to spot automatic cascades of thoughts and reactions. Many stressors are self-imposed by the doing mode of processing and are not necessarily immediately apparent, and need not be overtly catastrophic in nature to nevertheless cause burden. Mindfulness highlights moments that might subconsciously cause grief, if left unattended. When an individual starts thinking about negative interactions at work, or ends up getting distracted by e-mail or the Internet, it can leave him or her open to potentially negative moods or detract from the time spent on more valuable aims and goals (Brown and Ryan, 2003). These kinds of moments add up over time, thus identifying them is valuable to reducing tension and opening up new ways of responding. The stressor is made visible and, in being so, it can be prevented from causing additional burden by letting go or directly addressing the issue, allowing stress to return to its adaptive role.

There is an important distinction to be made between the stressors themselves and the appraisal of said stressors. The role that perceived stress plays in the stress response can be as stressful (and sometimes more stressful) than the actual threat itself. Mindfulness has the potential to alter the way in which both stress and the stress response are experienced. In a review, Thompson et al. (2011) found that mindfulness is a strong predictor of resiliency following exposure to trauma. Participants

with higher levels of mindfulness exhibited fewer disruptive symptoms following trauma while those who developed post-traumatic stress disorder (PTSD) were more likely to use avoidant coping strategies and showed higher levels of dissociative experiences, common of PTSD. Similarly, in a four-part study, student stress was measured via stress tests, autobiographical stress recall, experience sampling in daily life, and over the course of a semester leading up to exams. Weinstein et al. (2009) found that mindful students were less susceptible to stressful experiences, reporting more muted stress appraisals and showing better performance. They also used approach coping skills to deal with stressful situations whereas those low in mindfulness tended to utilize avoidant coping strategies.

Individuals who score higher on measures of mindfulness may have higher tolerance to distress because they are more likely to see the stressor at face value (not to elaborate and catastrophize), are less overwhelmed by their own thoughts, and are able to identify and respond to stress adaptively (Feldman et al., 2013). With the growing understanding of the absolute detrimental impacts of stress, the examination of practices and behaviors that can mitigate the levels of experienced stress are essential. The attentional shift that comes with dedicated practice, like any other acquired skill, can be reinforced over time, and it is becoming evident that mindfulness is a skill worthy of our scientific attention.

Mineral Resources, Limits to: The Case of Peak Oil

Ugo Bardi, Università di Firenze, Firenze, Italy

© 2015 Elsevier Ltd. All rights reserved.

Abstract

This article reviews the concept of 'peak oil' showing that it is a consequence of a combination of geological and economic factors that are normally present when exploiting a finite resource under a free (or nearly free) market conditions. The concept of peak oil is then analyzed in view of the reactions to the concept during the more than half a century from its introduction. There have been several similar cases in the past where the attitude of the public and the operation of industrial lobbies has led to the demonization of a number of studies and of the scientists who performed them. In the case of peak oil, this negative reaction has not been so strong as in other cases, but still the general reaction shows several similarities with examples such as, for instance, the 'Limits to Growth' study of 1972 and climate science today.

Introduction

The term 'peak oil' refers to the idea that the world's production of crude oil is expected to peak and then decline, typically when about half of the available resources have been extracted. The term was proposed for the first time in 1999 by Colin Campbell in the first issue of the newsletter of the Association for the Study of Peak Oil (ASPO) (Aleklett, 2009). Campbell, together with his colleague Jean Laherrere, had proposed earlier on (Campbell and Laherrere, 1998) that the world's production of crude oil world peak and decline approximately in 2005, on the basis of a previous concept suggested by Marion King Hubbert (1956).

The concept of 'peaking' and 'peak oil' rapidly gained recognition with the start of the second oil crisis in the first decade of the twenty-first century and it became an icon of the movement of ideas that sees the depletion of nonrenewable mineral resources as a major problem for humankind's future. In time, the peak oil idea generated a number of similar concepts, such as 'Peak Coal' (Patzek and Croft, 2010; Zittel et al., 2013), 'Peak Uranium' (Dittmar, 2013; Zittel et al., 2013), 'Peak Minerals' (Bardi and Pagani, 2007), 'Peak Caviar' (Bardi, 2008), and even 'Peak Everything' (Heinberg, 2007). All these concepts are based on the same interpretation of the trend of exploitation of a resource that exists in limited amounts or that, anyway, is exploited much faster than it can regenerate itself.

'Peak Oil' is the best known of these peaks and it is a classic example of a message related to the finiteness of natural resources. As it is normally understood by the public, it deals with something relatively easy to understand: given that the amount of extractable hydrocarbons in the world is limited, there should follow as a simple inference that, at some moment in the future, production will go to zero. As production started at zero in the past, there has to be a maximum somewhere in between and we can call it a peak.

In this sense, the issue of peaking differs from other issues also related to the finiteness of our environment, which are often more difficult to explain to the general public. For instance, climate change can be seen as related to the limited capability of the Earth's atmosphere to absorb greenhouse gases without heating up at levels dangerous for the survival of human beings. But most people perceive the problem of climate change as complex, abstract, and remote from their daily experience and hence not an immediate threat.

Nevertheless, the concept of peak oil is widely misunderstood and the debate on it in the media goes through the usual oversimplifications. The concept of 'peak' is often confused with the actual 'running out' of a resource. The exact date of the peak is given unduly importance; neglecting the fact that it is gradual depletion that counts and, in particular, the rising costs of exploiting the resource. Also, as it often happens with negative messages, those who propose the idea of peak oil are the object of personal attacks and are often branded as catastrophists or Cassandras. The result is that the message arrives garbled and confused to the public and to policy makers alike.

In this article, I will provide an overview of the concept of peak oil that can be used to understand the more general concept of resource depletion. In addition, I will provide a discussion on how people have reacted so far to the concept of peak oil, which turns out to have been similar to the reaction to other 'negative' views of the future, such as global warming, environmental poisoning, and the like.

A Brief History of the Concept of Resource Depletion

It was only in mid-nineteenth century that the first analysis of the consequences of the limited amounts of mineral resources available was published. It was the economist William Stanley Jevons who produced it in his *The Coal Question; An Inquiry Concerning the Progress of the Nation, and the Probable Exhaustion of Our Coal Mines* (1865) (Jevons, 1866).

Jevons' study was grounded in a well-known concept in economics, that of the 'diminishing returns on investments.' In order to extract coal, one must invest resources in the form of equipment, machinery, work, and more. In Jevons' times, most of these resources were produced using coal and, hence, one could say that coal needs to be invested to obtain coal. So, extraction as an economic activity is subjected to the conventional concept of return on investment (ROI). In modern terms, the same concept can be seen in energy terms, that is as 'energy return on energy investment' (EROI or EROEI) (Hall and Day, 1990).

The basis of Jevons' interpretation lies in the fact that, for all investments, the high return ones are those made first. That is,

the coal deposits closest to the surface and richest in coal were those which provided the highest returns (and needed the least energy investments) and hence were extracted first. With time, however, extraction had to move to less satisfactory resources, that is to thinner and deeper coal seams. That required larger investments and it lowered the returns. Hence, Jevons proposed that, in time, coal extraction would become less and less convenient in terms of monetary returns and also in terms of resources to be invested. At some moment, coal production would cease to grow and then enter in a phase of permanent decline. That would occur well before the actual disappearance of the extractable coal deposits in Britain and, according to Jevons, 'within a century from the present time' (Chapter XII of *The Coal Question*). Jevons predictions turned out to be qualitatively correct, as shown by the historical data (**Figure 1**).

After Jevons' work, the interest in understanding mineral depletion lied dormant for several decades and it was only in the twentieth century that new theoretical studies were performed on the subject. In the 1930s, Harold Hotelling introduced the so-called 'Hotelling's rule' (Hotelling, 1931), proposing that the prices of an exhaustible resource would keep growing with the progress of depletion and that production would decline from the beginning of the extraction cycle. This result made the model even more 'doomerish' than Jevons' one. A more optimistic theory was developed in later times on the basis of neoclassical economics, see, for example, Solow (1974) and Stiglitz (1979). The gist of this interpretation is that the same production levels of any commodity can be obtained by different combinations of elements; for example, number of workers, equipment. It is further assumed that these elements are wholly interchangeable with each other. There follows that the production of a mineral commodity can continue growing even for a diminishing availability resulting from depletion, provided that technological progress increases more rapidly with time; as it was proposed to be the general case (Nordhaus, 1992).

Even more optimistic models, albeit qualitative ones, were also developed. The so-called functional model of resource extraction (Zimmermann, 1933) emphasizes the fact that higher prices make it possible to extract more expensive resources, thus increasing the resource base. This concept is often expressed as 'the market creates resources.' According to this view, high prices do not depress demand because technological progress always makes it possible to reduce extraction costs and, in any case, a growing economy can maintain a healthy demand even for high prices. This interpretation seems to be rather popular in many circles but it may lead to some rather overoptimistic interpretations, such as when the economist Julian Simon stated (Simon, 1981) that the world's mineral resources would last 'six billion years' or anyway for times so long that there would be nothing to fear even for a remote future. Simon's interpretation originated, apparently, from the examination of the price trends of just five mineral commodities over a few decades.

The problem with most of these models of depletion is that they are either abstract and scarcely connected with the real world or qualitative and based on unverifiable assumptions. For instance, the neoclassical model was criticized by Herman Daly (1997) as:

> Since the production function is often explained as a technical recipe, we might say that Solow's recipe calls for making a cake with only the cook and his kitchen. We do not need flour, eggs, sugar, etc., nor electricity or natural gas, nor even firewood. If we want a bigger cake, the cook simply stirs faster in a bigger bowl and cooks the empty bowl in a bigger oven that somehow heats itself. Nor does the cook have any cleaning up to do, because the production recipe produces no wastes.

Figure 1 Historical data for British coal production. The data from 1815 to 1860 are from Cook, C., Stevenson, J., 1996. The Longman Handbook of Modern British History, 1714–1995. Longman, London and New York., the data from 1860 to 1946 are from Kirby, M.W., 1977. The British Coal-mining Industry, 1879–1946. The Macmillan press Ltd, London and Basingstoke., and the remaining data are courtesy of the British Coal Authority (http://coal.decc.gov.uk/). The data have been fitted with a Gaussian function that approximates the Hubbert curve (see text for a description).

Probably as an effect of the limitations of these models, the extractive industry normally maintains a 'down to earth' approach to forecasting; mainly focused on the determination of the extractable amounts on the basis of geological data which are then projected into the future on the basis of the concept of 'resource to production' (R/P) ratio. This ratio returns the number of years of production still available at constant production rate and it can not tell much about long-range trends.

However, in the 1950s, Marion King Hubbert went beyond this low key approach and developed a long-range predictive model based on resource estimates. The model, published for the first time in 1956 (Hubbert, 1956), was based on the idea that the oil extraction cycle was to follow a symmetric 'bell-shaped, curve. That is, it would grow up to a certain point (the 'Hubbert peak') and then gradually decline on the other side of the curve. The model for the US 48 lower states is shown in Figure 2.

Today, it is possible to examine historical cases of regional oil production in light of the Hubbert model. There are many cases in which the model does describe the historical oil production data and can be used for forecasting. Its most notable success is for oil production in the United States up to just a few years ago. But the model works not just of oil; it can also describe other nonrenewable mineral resources (Bardi and Pagani, 2007) and even the production trends of renewable resources when they are exploited at rates much faster than their replenishing rate, for example, whale oil (Bardi, 2007). However, in many cases, the results of the Hubbert model turned out to be approximate or even completely unable to describe historical data (Brandt, 2007). Production in countries such as Saudi Arabia never showed a well-defined bell-shaped curve, while in other cases the data could only be fitted by multiple curves; such as for the Soviet Union and, probably, for the United States in recent years.

Hubbert's ideas were reexamined in 1998 by Jean Laherrere and Colin Campbell (Campbell and Laherrere, 1998) who used the model to analyze the pattern of the world oil production. Their prediction was that a world peak production for conventional crude oil (peak oil) would occur approximately in 2005. This date did correspond to a considerable slowdown of the precedent growth trends and a rapid rise in oil prices. However, it is also true that at present (2014) a well-defined productive peak is not yet visible. One of the problems lies in the fact that Campbell and Laherrere based their forecast on 'conventional' oil, whereas in recent years the industry has been able to put into production various sources of 'non conventional' oil, including biofuels, liquids from tar sands, and others. The addition of these resources has permitted to keep increasing the production of combustible liquids, albeit at a slower rate than in the past. The following figure (Figure 3) shows the updated forecast for world oil production obtained using the same methods that were used for the 1998 study (Campbell and Laherrere, 1998)

The Systemic View of Peak Oil

In time, several attempts were performed to understand the theoretical basis of the Hubbert model. Here it would be out of place to review all these studies; it will suffice to say that the Hubbert ideas have been examined by means of standard economics models (see, e.g., Holland, 2013), on statistics interpretations (see, e.g., Guseo, 2011), and by 'bottom up' models based on the extraction dynamics of wells (Bentley, 2002). These attempts have had various degrees of success, but for the present text it may be more interesting to focus into an interpretation that can provide an intuitive grasp of the elements that create the bell-shaped curve, in other words, a 'mind sized' model (Bardi, 2013). Such a view of the model can be based on the concept called 'system dynamics'.

System dynamics originated in the 1960s, mainly with the work of Jay Forrester (1995). Using the newly developed digital computers of the time, Forrester put together a complete method for the study of the evolution of complex systems. The method was based on the simultaneous solving of a set of differential equations that described how the various parameters of the system interacted with each other as a function of time. These systems were often studied in terms of long-term trends of social and economic systems and, in this application, system dynamics was never to be intended as a forecasting method. Rather, it was to be seen as a method for

Figure 2 Hubbert's original graph illustrating the proposed production curve for crude oil in the 48 US lower states. Reproduced from Hubbert, M.K., 1956. Nuclear energy and the fossil fuels. In: Spring Meeting of the Southern District Division of Production American Petroleum Institute. American Petroleum Institute, Sant Antonio, TX. Available at: energycrisis.biz/hubbert/1956/1956.pdf (accessed 03.12.12.).

Figure 3 Past world conventional crude oil and 'all liquids' production, together with an extrapolation for the future based on the Hubbert model. The peak for the production of regular oil may have taken place in 2005, but the total peak for all possible forms of combustible liquids will not occur until *c.* 2015. Data courtesy of Colin Campbell.

amplifying the power of the human mind in understanding the behavior of complex systems and how to modify it (Meadows, 2008).

System dynamics was soon utilized to describe the behavior of the whole world's economic system, an approach often termed 'world modeling.' The first study in this field was performed by Jay Forrester (1971), soon followed by the 1972 study titled *The Limits to Growth* (Meadows et al., 1972) (LTG) which rapidly became a major subject of debate worldwide (Bardi, 2011b). The LTG model did not consider crude oil as a disaggregated resource, but its general results were consistent with the earlier model proposed by Hubbert. That is, system dynamics predicted that production would grow at a near exponential rate for a while, then slow down, reach a peak, and finally decline. The shape of the LTG production curves, however, was typically asymmetric; with decline faster than growth. The reasons for this behavior are described by Ugo Bardi (2013) in terms of a property of these systems termed the 'Seneca Effect' that results from parameters additional to depletion affecting the production trends.

Seen in these terms, the concept of peak oil is best understood in terms of system dynamics. A simple interpretation in this sense has been presented by (Bardi and Lavacchi, 2009). In short, the bell-shaped curve is generated by increasing extraction cost which lower profits. As a result, the industry finds itself short of the necessary capital to invest in more and more expensive resources. With diminishing investments, the production rate peaks and declines. This interpretation is equivalent to the one proposed by Jevons (1866) with the difference that when these assumptions are set in the form of equations in the model, they do generate the bell-shaped curve typical of Hubbert's model. This interpretation of the model can also be used to understand why the Hubbert model may not work for some regional cases. It is because the economic and financial systems are able to move resources from one sector of the economy to another. Increasing investments have permitted, for instance, to keep gas production from decreasing in the United States after having peaked in 1973 (Bardi, 2011a). In recent years, large investments on the extraction of 'tight gas' have allowed the US industry to produce at levels exceeding those of the peak.

Perception and Reactions to Peak Oil and Other Depletion Claims

The diffusion of new concepts in science tends to follow well-established patterns. Basically, ideas that challenge the establish paradigms tend to undergo thorough (and sometimes aggressive) scrutiny on the part of the scientific community. Surviving this scrutiny may be difficult for a new theory which, often, needs time and more data to be refined and upgraded in such a way to become acceptable. A classic case in point is the reaction to Alfred Wegener's theory of 'continental drift' that was proposed for the first time in 1912 (Wegener, 1912). As reported in detail, for instance by Oreskes (1999), Wegener's theory went through several stages: it attracted wide attention at the beginning, but it was then strongly criticized and rejected. Different factors played a role in the rejection of the theory, including political ones (Wegener was German and German science was not popular for a long time in the periods after the two world wars). But the rejection was not unjustified: before accepting the idea that continents were moving, some serious evidence was needed for their motion and for the causes of it. This evidence was not available in Wegener's times but when appropriate data became available, in the 1970s, Wegener's theory became the cornerstone of modern Earth sciences, today renamed as 'plate tectonics.'

So, the acceptance of new scientific ideas seems to follow some established gradual patterns and Bardi has argued that a similar path should be expected for the peak oil theory (Bardi, 2009). However, the situation may be more complex than that. In modern times, the negative reaction to new and upsetting paradigms can be enhanced by public relation campaigns specifically aimed at discrediting the research and the researchers involved. There are several examples of such campaigns in recent history, some of which have been highly successful. Here is a list of some of the best known and relevant cases.

1. *'Silent Spring' and the pesticide industry*. In 1962, Rachel Carson published a book titled *Silent Spring* (Carson, 2002) in which she strongly criticized the abuse of pesticides. The reaction of the chemical industry is described by (Groshong, 2007) reporting the text of a document Manufacturing Chemists' Association, Inc. that discusses "measures which should be taken to bring the matter back to proper perspective in the eyes of the public." This is one of the first documented cases of a planned PR campaign by an industry against a scientist and of her results.
2. *The tobacco controversy*. In the 1960s, the tobacco industry fought hard and for several years against the studies that had evidenced a link between tobacco smoking and lung cancer. The story of the PR campaign generated by the tobacco lobby is told in detail, for instance, in 'Bending Science' (McGarity and Wagner, 2008). This campaign is one of the most detailed set of data available on the way these campaigns are set up and operated.
3. *The 'Limits to Growth' controversy*. When the study titled *The Limits to Growth* (Meadows et al., 1972) was published, it encountered considerable criticism in various scientific sectors. However, as detailed in (Bardi, 2011b) it was not the scientific criticism that condemned the study to be widely considered as 'wrong' but, rather, a denigration PR campaign that had many points in common with other cases of denigration of scientists and of scientific studies. In this case, however, there is no actual evidence that the campaign was financed by specific lobbies and groups.
4. *The climate controversy*. The story of this controversy is recent and still ongoing. Data that demonstrate the occurrence of anthropogenic climate change (AGW) have been accumulating since the mid-1950s. By the 1980s, the evidence was sufficiently ample that it led to the foundation of the International Panel on Climate Change (IPCC, established in 1988) that issued its first report in 1990 (Houghton et al., 1990). It is certain that there was an organized reaction on the part of some sections of the fossil fuels industry against the concept of anthropogenic climate change. This reaction involved methods and techniques very similar to those deployed by the tobacco industry in earlier times, as described for instance in *Merchants of Doubts* (Naomi Oreskes and Conway, 2010) and *Climate Cover-up* (Hoggan, 2009).

If we examine the concept of 'peak oil' in light of these controversies, we see that it does not appear to have been the object of comparable professional negative campaigns. From the beginning, the theory was considered mainstream enough to be mentioned and discussed in scientific journals. For instance, a 1974 article on *Science* (Berg et al., 1974) extensively covers Hubbert's estimates, even though it concludes that they are excessively pessimistic. However, with the fall in oil prices in the second half of the 1980s, interest in oil depletion waned, only to be taken up again with the end of the 1990s and the new century. In this second wave of interest, the discussion in scientific journals ranged over a wide variety of issues, with the main criticism being that of the concept of 'peaking' on the basis of the uncertainty in the reserve estimates (see, e.g., Lynch, 1999, 2002).

As shown in **Figure 4**, obtained from the Jstor database (dfr.jstor.org) that collects scientific article over more than a century, the interest in Hubbert's idea seems to have ebbed and waned in correspondence to the vagaries of the oil prices.

Figure 4 Fraction of citations in the Jstor database (dfr.jstor.org) that include the terms 'Hubbert,' 'peak,' and 'oil.'

We clearly see in the picture the peaking of interest in Hubbert's theory during the 'oil crisis' of the 1970–80s. The interest wanes during the period of low oil prices in the late 1980s and the 1990s, to pick up again in recent times, with the new oil crisis ongoing. Neither the data about Jevons nor those about Hubbert tell us whether the citations indicated acceptance or rejection of the concept discussed, but it is clear that if the theory was mentioned in a scientific journal, it was considered at least worth discussing.

Outside the world of standard scientific journals, the concept of peak oil was often attacked and criticized in industry reports and in the media, for instance, by Daniel Yergin (2011) and Leonardo Maugeri (2012). The reaction against the perspective of scarcity brought by peak oil also originated a series of legends often based on the idea that oil scarcity is a conspiracy on the part of the oil industry as a way to justify high market prices. This legend is often correlated with the so-called abiotic oil theory; often interpreted in terms the existence of large, even immense, oil resources located inside the Earth's mantle; something that, incidentally, makes no sense even in simple physical terms, as discussed in Höök et al. (20101).

So, even without evidence for a major PR effort against the concept of peak oil, these reactions shows the difficulty that the human mind has to deal with even moderately complex concept that are not amenable to simple, binary, 'yes/no' answers. It is a common experience in trying to relate the concept of 'peak production' to the general public or to policy makers, to face an attitude that could be defined as 'binary,' in the sense that the depletion problem is seen as an 'either/or' condition. That is, either there is oil (or some other resource) or there is not. In the first case there is no problem, in the second we have an immediate problem. This attitude reminds the statement attributed to Arthur Schlesinger "Human beings have only two modes of operation: complacency or panic." It has also been examined by Donella Meadows (1999) who cites Jay Forrester about two common modes of thought: 'dynamic' and 'linear.' According to this interpretation, linear thinking is the one that sees the world in binary terms of black/white, yes/no, good/bad, full/empty, and so on, and it lacks the nuances of dynamical thinking which instead sees the world in various shades of gray and the glass as always half full or half empty. Despite the increasing complexity of the modern world, the linear mode of thinking seems to be still largely prevalent.

Conclusion

All models are wrong, and the Hubbert model is no exception. But, all models can be useful if one understands their limits. What the Hubbert model of oil production can tell us is that the limit to the production of a mineral resource lies not with the concept of 'ultimate recoverable resource' but with the increasing costs of extraction that start manifesting themselves much before the last barrel is extracted. If left to itself, the extractive system will often follow a Hubbert-like path, but that is not obligatory; you can beat Hubbert, but you must be prepared to pay a high price for doing that. But it is also true that you cannot beat Hubbert forever by playing the extraction game harder: increasing energy costs of extraction are a physical factor that eventually forces the decline of a limited resource. The market can make extraction profitable, but it cannot make it cheap. What we *could* do to beat Hubbert forever is to leave the extraction game altogether. We would need to plan ahead and start already now to use renewable energy resources – not subjected to depletion – on a large scale. But human beings do not seem to be especially apt at long-range planning and the destiny of those who do not understand the Hubbert curve seems to be to follow it to the bitter end.

Minimum Wages

William Wascher, Board of Governors of the Federal Reserve System, Washington, DC, USA

Published by Elsevier Ltd.

Abstract

The minimum wage is a policy commonly used in both advanced and emerging market economies to support the wages of low-wage workers and to increase the income of the poor. However, the efficacy of the minimum wage as a policy tool is controversial. Although minimum wages do raise the wages of low-skilled workers, they also reduce employment opportunities for such workers and raise the prices of goods and services produced with low-wage labor. On balance, minimum wages appear to have little, if any, beneficial effect on the distribution of income.

Introduction

Minimum wage laws specify the minimum rate that a worker covered by the law can be paid. Minimum wages are commonly set by governments in both advanced and emerging market countries in an attempt to prohibit unfairly low pay and increase the income of workers at the low end of the wage distribution. First used in Australia in the late 1800s to combat manufacturing 'sweatshops,' minimum wages subsequently were introduced in the United Kingdom and the United States in the early part of the twentieth century and have since been implemented in many other countries. According to the International Labour Organization (2012), more than 130 countries around the world currently have a minimum wage of some type, although the specific levels of minimum wages, their coverage, and the processes used to determine them can differ substantially across these countries.

Proponents of the minimum wage argue that it is an important policy tool aimed at ensuring that workers receive a 'fair' wage for their work and helping individuals or families achieve self-sufficiency through the workplace. And, indeed, minimum wages are very popular among the public because they raise the wages of many low-skilled workers. However, while supportive of the goals of minimum wages, many economists are less sanguine about their likely effects on the low-wage labor market. They note that minimum wages increase the costs to firms of employing low-skilled labor, which can induce employers to reduce their hiring or raise prices, offsetting many of the economic benefits of higher wages. In addition, they point out that many minimum wage workers are not from poor families, limiting the effectiveness of the policy tool in alleviating poverty. In this sense, the minimum wage creates economic winners and losers, and the welfare consequences of such a policy depend on who comprises each group.

Characteristics of Minimum Wage Laws

Although in widespread use around the world, the characteristics of minimum wage laws and how they are determined are different across countries. In many countries, the minimum wage is a national standard set by federal government legislation or statute; this is the case, for example, in Australia, France, and several southern European countries. In other countries, such as Canada and Japan, minimum wages are set at the regional level. And a few countries, including the United States, have both a national minimum wage and wage floors set by narrower geographic jurisdictions, such as states or cities. In addition, while minimum wages in many countries are determined as part of the legislative process, in other countries the minimum wage may be determined through a national collective bargaining process consisting of representatives from employee and employer groups, as well from the national government.

Even apart from these differences in the wage-fixing process, the effective level of the minimum wage varies widely around the world. The International Labour Organization defines the minimum wage as "the payment to the employed of a wage adequate to maintain a reasonable standard of life as this is understood in their time and country" (ILO, 2012: p. 1). In practice, however, minimum wages may differ across countries according to the political climate and in response to varying concerns about the unintended consequences of setting a wage floor on employment and, more generally, the competitiveness of firms that employ low-wage labor. Moreover, even the concept of a minimum wage is not standard: While minimum wage laws refer specifically to the base wage in many countries, in others wage supplements – such as tips, commissions, or productivity bonuses – are counted toward the minimum wage.

In addition, the proportion of workers covered by minimum wage laws also differs substantially across countries. In many countries, all workers are covered by minimum wage legislation and all employers are subject to those laws. In other countries, however, certain groups of workers are exempt from the minimum wage or can be paid a legislated subminimum wage below the normal minimum wage. In particular, youths or trainees can sometimes be paid less than the regular minimum wage, while household workers and others working in the informal sector are often excluded from minimum wage laws.

Economic Effects of Minimum Wages

The economic effects of minimum wages have been studied extensively by economists over the past century. Despite the

attention afforded this issue, economists remain divided on the merits of the minimum wage. In part, this may reflect the fact that theoretical models of the labor market differ in their implications for the effects of the minimum wage on employment, income, and prices. More importantly, empirical studies have yielded a wide range of estimated effects. However, an extensive review of the minimum wage literature by David Neumark and William Wascher (2008) concluded that "minimum wages reduce employment opportunities for less-skilled workers" and "do not, on net, reduce poverty or otherwise help low-income families" (p. 6). A more recent review of the U.S. literature by the United States Congressional Budget Office (2014) also concluded that a higher minimum wage would likely result in fewer jobs for low-wage workers, although this review concluded that a higher minimum wage would reduce the number of families with incomes below the poverty line.

Theoretical Considerations

The majority of research on minimum wages – both theoretical and empirical – has focused on their effects on employment. In the simplest textbook model of the labor market, in which labor and product markets are assumed to be perfectly competitive, the equilibrium wage is determined in the marketplace so that the supply of labor is equal to the demand for labor (point L in **Figure 1**). If all workers are covered by the minimum wage, setting the minimum wage above the equilibrium wage leads to a decline in employment through a reduction in the demand for labor (point L_{MW} in the figure). This reduction in labor demand occurs through two distinct mechanisms. First, the minimum wage increases each firm's cost of production, and thus leads to a rise in the price of output, which, in turn, induces a decline in demand for it. In response to the weaker demand for output, production falls, reducing the demand for labor (this is referred to as the 'scale effect'). Second, in response to the higher cost of labor induced by the minimum wage, employers adjust their production processes to shift the mix of inputs they use away from labor toward capital and other inputs (this is referred to as the 'substitution effect'). Moreover, in competitive models with more than one type of labor, firms will substitute away from the low-skilled workers toward higher-skilled workers whose wages are unaffected by the minimum wage ('labor–labor substitution'). The combined result of these responses is a decline in employment of low-skilled workers who are covered by minimum wage laws.

Figure 1 The textbook treatment of minimum wages.

Note that the effects on unemployment can be ambiguous in many of these models. In the simple textbook model with full coverage illustrated in **Figure 1**, a higher minimum wage causes labor demand to fall and labor supply to rise, resulting in an increase in unemployment. However, in a model in which not all sectors of the economy are covered by a minimum wage, workers displaced by the minimum wage in the covered sector may take a job instead in the uncovered sector or drop out of the labor force, mitigating the effect of the higher minimum wage on unemployment in the aggregate. Alternatively, the higher minimum wage in the covered sector may induce individuals in the uncovered sector to search for work in the covered sector, thereby increasing the supply of labor to the covered sector and exacerbating the effect on unemployment.

In addition, not all theoretical models of the labor market predict that minimum wages will reduce the demand for low-skilled labor. In particular, in so-called 'monopsony' models that assume that employers have market power over their workforce, an increase in the minimum wage can, under certain conditions, lead to an increase in employment (Stigler, 1946). In such models, when individual employers have to raise the wage to hire an additional worker, they must also increase the wage paid to existing employees. Absent a minimum wage, this condition implies that the market-determined level of employment and the market-determined wage will fall below those in the competitive model. In this case, imposing a minimum wage between the monopsony wage and the competitive wage will lead to an increase in employment, although, it is still the case that boosting the minimum wage above the competitive equilibrium wage will begin to reduce employment for low-skilled workers, as predicted by the competitive model.

Empirical Evidence on the Employment Effects of Minimum Wages

Empirical research on the minimum wage dates back to the early 1900s, when economists at the U.S. Department of Labor investigated the effects of a new minimum wage law introduced in Oregon in 1913. Throughout the next several decades, and in particular, following the establishment of a national minimum wage in the United States in 1938, economists continued to evaluate the effects of minimum wages on employment with varying results. Of particular note was the so-called 'marginalist' debate, in which George Stigler and others argued that the results from minimum wage studies supported the neoclassical view that minimum wages reduce labor demand, while Richard Lester and others viewed the evidence as supporting the institutionalist view that marginal costs were not an important determinant of low-wage employment.

Following a series of minimum wage increases in the 1960s and 1970s and given the ongoing debate about their effects, the United States Congress established the Minimum Wage Study Commission in 1977 to investigate "the effects of increasing

the minimum wage on inflation, employment, and unemployment; the ability of the minimum wage to ameliorate poverty; and the economic consequences of proposals for automatic indexing of the minimum wage and for setting a special subminimum rate for young workers" (Eccles and Freeman, 1982: p. 226). As part of that effort, three of the Commission's staff economists surveyed the existing literature and did their own research, eventually publishing a summary concluding that "time-series studies typically find that a 10 percent increase in the minimum wage reduces teenage employment by one to three percent," with smaller effects evident for 20–24 year olds (Brown et al., 1982). This study was widely viewed as having settled this issue and became the 'consensus' view of economists for the next decade or so.

In the early 1990s, however, the debate over the effects of the minimum wage reemerged. Armed with additional statistical variation generated by an increasing number of states with a minimum wage set higher than the federal level, a new set of researchers began to reassess the effects of the minimum wage on employment. In contrast to the time-series literature summarized by Brown et al., the evidence from this new research varied widely, with some researchers finding results that supported the consensus view (e.g., Neumark and Wascher (1992), Deere et al. (1995), and Burkhauser et al. (2000)), others finding no significant effects of minimum wages (Card, 1992a), and still others reporting positive effects on employment from a higher minimum wage (Card, 1992b; Katz and Krueger, 1992; Card and Krueger, 1994, 1995).

In an effort to synthesize this literature, David Neumark and William Wascher published a critical summary of the empirical literature on minimum wages that had been produced since the late 1980s (Neumark and Wascher, 2008). While acknowledging that the range of estimates in the more recent literature was noticeably wider than in the literature reviewed by Brown et al., Neumark and Wascher concluded "that the preponderance of evidence supports the view that minimum wages reduce the employment of low-skilled workers" (p. 104) and that the "adverse effects are even more apparent when research focuses on those directly affected by minimum wages" (p. 287).

Subsequent to the review of the literature by Neumark and Wascher, a few economists have challenged their conclusions. One line of argument relates to the appropriate way to summarize a large body of empirical research. In particular, Neumark and Wascher conducted a critical review of the literature, in which they focused on what they viewed as the most compelling evidence on the effects of the minimum wage. In contrast, Doucouliagos and Stanley conducted a meta-analysis and concluded that once the results are adjusted for publication selection bias there is little evidence of an adverse effect of the minimum wage on employment. However, Neumark (2013) questions the relevance of the meta-analysis results in assessing the body of minimum wage research because that approach treats all studies as providing equally valid evidence on minimum wage effects, regardless of the reliability of the methodology used to conduct the analysis or differences in the set of workers on which the studies focus.

A second line of argument asserts that a failure of the literature to take account of 'spatial heterogeneity' led to a negative bias in the disemployment effects reported in many of the studies included in Neumark and Wascher's survey (e.g., Allegretto et al., 2011; Dube et al., 2010). In particular, these authors claim that spurious correlation between minimum wage increases in particular states and underlying changes in low-wage employment in those states confounds the ability of standard panel-data techniques to accurately estimate the effects of minimum wages on employment, and they find that including state-specific time trends or limiting the sample to states or counties in particular geographic areas leads to estimates of minimum wage effects that are small and not statistically different from zero. However, these arguments have themselves been criticized as based on overly restrictive specifications that throw out too much identifying information to attempt to eliminate a potential bias that is of questionable importance (Neumark et al., 2014).

As noted above, the latest researchers to weigh in with a summary of the employment effects of minimum wages in the United States are from the independent Congressional Budget Office (CBO). In a February 2014 report, the CBO assessed the existing body of research and concluded that an increase in the minimum wage from its current level of $7.25 per hour to $10.10 per hour "would reduce total employment by about 500 000 workers, or 0.3 percent" (p. 1). The agency also noted that the standard error around this estimate is quite wide with "about a two-thirds chance that the effect would be in the range between a very slight reduction in employment and a reduction in employment of 1.0 million workers."

The controversy over the employment effects of minimum wages has not been limited to the United States. Although the majority of research in this area has tended to focus on U.S. labor markets, reflecting the long history of the federal minimum wage in the United States as well as the greater variation available from state-level minimum wages, there is a burgeoning literature on the effects of minimum wages in other countries. As in the United States, however, a consensus on the effects and thus the appropriate level of the minimum wage remains elusive, with ongoing debates in many countries, including the United Kingdom, France, Australia, and most recently Germany.

Effects of Minimum Wages on Poverty and the Distribution of Income

Although the employment effects of the minimum wage has received the most attention in the research on the implications of setting a floor on wages, the potential for job loss is not the only, or even necessarily the most important, outcome from raising the minimum wage. Many of those who support a higher minimum wage claim that they do so because, in their view, it will help low-income families by providing them with additional income that outweighs the possible negative consequences on overall employment. This challenge of balancing the potential benefits against the possible adverse employment effects of the minimum wage was eloquently captured nearly four decades ago by Edward Gramlich (1976), who wrote "Minimum wages do, of course, distort relative prices and hence compromise economic efficiency, but so do all other attempts to redistribute income through the tax and transfer system. The important question is not

whether minimum wages distort, but whether the benefits of any income redistribution they bring about are in some political sense sufficient to outweigh the efficiency costs" (p. 410).

Despite the compelling rationale for focusing on the effects of minimum wages on the distribution of income, research on this aspect of minimum wages is much less developed than the research on employment effects. However, what research does exist tends to find little net benefit from a higher minimum wage on the incomes of poor and near-poor families, with some studies finding modest positive effects (Dube, 2013) and others finding no effects or even modest negative effects (Neumark et al., 2005). According to Neumark and Wascher (2008), "the combined evidence is best summarized as indicating that an increase in the minimum wage largely results in a redistribution of income *among* low-income families, with some gaining as a result of the higher minimum wage and others losing as a result of diminished employment opportunities or reduced hours" (p. 189).

There are three reasons for this result. First, the minimum wage is not well targeted toward the poor because many workers who earn the minimum wage are not in poor families. For example, Burkhauser and Sabia (2010) find that only 11.3% of minimum wage workers were in poor families in 2007, while 42% were in families with incomes more than three times the poverty line. Second, roughly 50% of poor families have no workers at all. These families are obviously not in a position to benefit from a higher minimum wage. And third, as discussed earlier, a minimum wage increase is likely to lead to adverse employment effects on low-wage workers in poor families, offsetting the social benefits of the higher wages earned by those workers who keep their jobs. In the end, the recent CBO report concludes that the minimum wage would have a modest positive effect on the income of households below the U.S. poverty line, but also notes that the minimum wage is less effective at redirecting income toward the poor than some other policies, such as the Earned Income Tax Credit.

Other Effects of Minimum Wages

From a theoretical perspective, minimum wages can also affect other economic outcomes, including human capital acquisition and pricing behavior. For example, if a higher minimum wage increases the opportunity cost of attending school, some individuals who qualify for a minimum wage job may choose to work at the higher wage and thus acquire less education than they would if the wages associated with the available job opportunities were lower. Similarly, if a worker's on-the-job training is implicitly financed by the firm paying a lower wage, then an increase in the minimum wage could cause employers to reduce the amount of training provided to its employees. Alternatively, a minimum wage could increase the motivation for a worker to obtain additional training or schooling to better qualify for the higher-wage job, especially if the minimum wage reduces the availability of those jobs. With regard to prices, standard competitive models predict that some of the higher labor costs incurred by a firm following an increase in the minimum wage will be passed through to the prices of its product. However, in other models of the labor market, including the monopsony model described above as well as some versions of search and efficiency models, minimum wages can lead to a decline in prices, generally because these models predict an increase in output as a result of the minimum wage.

The empirical evidence, while limited, generally supports the view that minimum wages reduce human capital accumulation, although this conclusion is not clear-cut. With regard to schooling, higher minimum wages tend to be associated with lower school enrollment rates (Neumark and Wascher, 2008). For training, the evidence is more mixed. Some studies suggest that minimum wages cause employers to cut back on training, while others find little effect in either direction. However, other research finds that minimum wages have adverse longer-run effects on the earnings of adults who were exposed to a higher minimum wage in their youths, consistent with the possibility that the minimum wage reduced human capital formation for those individuals in their formative years.

With regard to pricing behavior, the empirical evidence generally indicates that minimum wages tend to result in price increases of goods or services produced with low-wage labor, consistent with the competitive model of low-wage labor markets. For example, MacDonald and Aaronson (2006) find that restaurants, especially limited-service outlets (e.g., fast-food restaurants) increase prices in response to a higher minimum wage, with the largest effects in low-wage areas where the effect of the minimum wage on labor costs is likely to be the greatest. That said, the effect of minimum wages on aggregate inflation is likely to be relatively small in most developed countries, reflecting the small share of minimum wage workers in the overall workforce. The exception might be in developing countries where more workers are affected by the minimum wage (say if other wages are set as multiples of the minimum wage), and especially if minimum wages are indexed to overall inflation.

Conclusion

The use of minimum wages is widespread around the world. While the exact nature of the wage floor and how it is determined differs across countries in many respects, the basic goals of the minimum wage are essentially the same everywhere: to provide higher wages for low-skilled workers and to provide additional income to poorer households.

Although these goals are laudable and important, whether the minimum wage can achieve them to any meaningful degree is questionable. Minimum wages obviously do raise the earnings of many low-wage workers. But they also appear to have negative effects on employment, which may adversely affect job opportunities for other low-skilled individuals. Moreover, the minimum wage is not well targeted toward the poor, as many minimum wage workers are in families well above the poverty line and many poor families have no workers. As a result, higher minimum wages tend to have only modest effects on the incomes of poor households, especially after taking into account the higher prices of goods and service passed on to consumers as a result of the wage floor.

Minnesota Multiphasic Personality Inventory

James N Butcher, University of Minnesota, Minneapolis, MN, USA

© 2015 Elsevier Ltd. All rights reserved.

Abstract

The Minnesota Multiphasic Personality Inventory (MMPI)-2 is the most widely used personality inventory in clinical, forensic, and personnel assessment settings. It is a self-report personality inventory based upon items that address mental health symptoms, personality traits, and behavioral characteristics. The MMPI-2 provides mental health professionals with information that allows them to appraise psychological adjustment. Moreover, the test includes a number of self-report validity indices that allow the practitioner to determine the client's willingness and frankness to cooperate with the appraisal.

The MMPI, the Minnesota Multiphasic Personality Inventory, has had a long and successful tradition in personality assessment. The test was originally developed in the 1940s as a means of evaluating mental health problems in psychiatric and medical settings. The test authors, Starke Hathaway and J.C. McKinley, thought that it was important in evaluating patients' problems to ask them about what they felt and thought. Their instrument was a self-report inventory that included a very broad range of symptoms and behaviors and could be answered with a sixth-grade reading level. The MMPI was developed according to rigorous empirical research methods and rapidly became the standard personality instrument in clinical settings (Hathaway and McKinley, 1940). The popularity of the true–false personality inventory was in large part due to its easy-to-use format and to the fact that the scales have well-established validity in assessing clinical symptoms and syndromes (Butcher, 2011). The MMPI underwent a major revision in the 1980s resulting in two forms of the test – an adult version, the MMPI-2 (Butcher et al., 1989) and an adolescent form, MMPI-A (Butcher et al., 1992). The MMPI-2 is the most widely researched instrument and is used for the evaluation of clinical problems in a broad range of settings including mental health, health psychology, correctional settings, and personnel screening, and in many forensic applications such as child custody and personal injury (Bow et al., 2010; Martin et al., 2001; Lally, 2003).

The MMPI-2 contains 567 true–false questions addressing mental health symptoms, beliefs, and attitudes. The items on the MMPI-2 are grouped into scales (clusters of items) that address specific clinical problems such as depression or anxiety. After the inventory is completed, the items are scored or grouped according to the scales that have been developed. An MMPI scale allows the clinician to compare the responses of the client with those of thousands of other people. Initially, the scores are compared with the normative sample, a large representative sample of people from across the United States, to determine if the person's responses are different from people who do not have mental health problems. If the person obtains scores in the extreme ranges, for example, on the depression scale, compared with the normative sample then they are likely to be experiencing problems comparable with the clinical samples of depressed clients that have been studied.

Evaluating Cooperative Responding

In some situations clients might be motivated to present personality characteristics and problems in ways that are different than they actually are. For example, if people are being tested to determine whether or not they are 'sane' enough to stand trial in a criminal court case they might attempt to exaggerate symptoms or problems to avoid responsibility. Alternatively, people being evaluated in preemployment psychological evaluation might be inclined to present themselves in an extremely positive way to cover up problems. It is important, in MMPI-2 profile interpretation, to evaluate the way in which people approach the task of self-revelation. Are they sufficiently cooperative with the testing to produce a valid result? There are several indices on the MMPI-2 to address honesty and cooperativeness in responding to the items (Baer et al., 1995):

Cannot Say Score

This index is simply the total number of unanswered items. If the client leaves out many items on the test (e.g., 30 items), the profile may be invalidated. A high score on this index suggests that clients have not cooperated sufficiently to provide a clear picture of their personality functioning.

The L Scale

The L or Lie scale is a measure of the client's willingness to acknowledge personal faults or problems. Individuals who score high on this scale are presenting an overly virtuous picture of themselves. They claim virtue and positive characteristics that are not typically found among people in general. The L scale is particularly valuable in situations where the individual has something to gain by not appearing to have problems, such as in personnel screening or in child-custody disputes. In these cases, people might try to put their best foot forward and present themselves as 'better' adjusted than they actually are.

The K Scale

The K scale was developed as a means of evaluating the tendency that some people have to minimize problems. This

 http://dx.doi.org/10.1016/B978-0-08-097086-8.25019-8

scale is also used as an index for correcting some clinical scales that have been shown to be affected by defensiveness; that is, it serves as a correction factor to compensate for the tendency of some people to deny problems. Empirically derived percentages of the K scale score are added to five of the clinical scales to improve test discrimination.

The Infrequency Scales

The MMPI-2 contains three measures to assess the tendency of some people to exaggerate their problems or 'fake' the test by overresponding to extreme items (the F or Infrequency scale, the Back F or F(B) scale, and the P(p) scale). Each scale performs a somewhat different function in interpretation. The items on these scales are very rare or bizarre symptoms. Individuals who endorse a lot of these items tend to exaggerate symptoms on the MMPI-2, perhaps as a way of trying to convince professionals that they need to have psychological services. Some people who have a need to claim problems to influence court decisions will tend to elevate the infrequency scales. The infrequency scales can be elevated for several possible reasons: the profile could be invalid because the client became confused or disoriented or responded in a random manner. High F and F(B) scores are commonly found among clients who are malingering or producing exaggerated responses in order falsely to claim mental illness.

TRIN and VRIN Scales

Two scales to assess inconsistent responding have been developed for the MMPI-2. These scales were derived by examination of the individual's responses to pairs of items that have similar content. A particular response to one of the items in the pair requires that the other item be endorsed in a given way to be consistent: for example, a pair of items that contains content that cannot logically be answered in the same direction if the subject is responding consistently to the content.

Profile Interpretation

The assessment of clinical problems is approached by examining the client's responses to the items using several strategies. We will examine three types of scales that comprise the MMPI-2's problem measures: the traditional clinical scales and profile codes, the MMPI-2 content scales, and the supplemental or specific-problem scales.

The MMPI-2 Clinical Scales

Hathaway and McKinley developed the original MMPI clinical scales to classify empirically or group patients into problem types. For example, they developed scales to assess hypochondriasis (the Hs scale), depression (the D scale), hysteria (the Hy scale), psychopathic deviation (the Pd scale), paranoid thinking (the Pa scale), psychasthenia (the Pt scale), schizophrenia (the Sc scale), and mania (the Ma scale). In addition, two other scales were included on the basic profile to address problems of sex-role identification (the Mf scale) and social introversion and extraversion (the Si scale). These scales have clearly defined correlates or empirical relationships. If a scale is elevated in the significant range, the individual is considered to possess the attributes measured by the scale.

Some clients have only one of the clinical scales elevated in their profile. In these cases, the profile interpretation is straightforward – the clinician simply examines the published correlates for that scale and incorporates these into the psychological report. However, some clients might have several of the clinical scales elevated in their profile. The full pattern or profile configuration needs to be interpreted. Fortunately, extensive research has been undertaken to evaluate complex profiles or code types. These profile types result from having two or more of the clinical scales elevated in the interpretive range. In these cases, the practitioner refers to published 'code books' which provide empirical descriptions for the various patterns that have been studied.

Content-Based Scales

The MMPI-2 contains a number of scales that assesses content themes that the individual endorsed in the item pool. The content scales are homogeneous item clusters that summarize themes and represent direct communications about problems to the practitioner. There are 15 content scales measuring different symptom areas and problems: for example, Antisocial Practices (ASP), Bizarre Mentation (BIZ), and Low Self-Esteem (LSE).

Special-Problem or Supplemental Scales

Several supplemental scales have been developed to assess specific problems such as the potential to develop problems of addiction (the MacAndrew Addiction scale or MAC-R and the Addiction Potential scale or APS) and whether or not the individual acknowledges having problems with drugs or alcohol. Another scale, the Marital Distress scale, addressed a client's attitudes toward their marital relationship. The MMPI-2 supplemental scales provide the practitioner with the means of evaluating specific problems (such as posttraumatic stress disorder) that are not addressed in the clinical or content scales.

Applications of the MMPI-2

Contemporary uses of the MMPI-2 include such activities as evaluating clients following their admission to an inpatient psychiatric facility; providing personality information about client's problems and attitudes in the early stages of psychological treatment to assess treatment amenability; providing personality information for therapists to employ in giving the client feedback in psychotherapy; and providing information that would aid the clinician in arriving at an appropriate clinical diagnosis. The MMPI-2 is also widely used in medical settings to provide psychological adjustment information on patients – for example, in rehabilitation programs as a measure of behavior problems and symptoms following a stroke as part of the neuropsychological evaluation; or in the evaluation of drug treatment effects.

A great deal of contemporary personality assessment research is also aimed at further exploring the MMPI-2 test

variables. The two most active research areas involve further exploration into the external validity of the MMPI-2 scales, and the translation and adaptation of the instrument for other languages and cultures. For example, research carried out in the mid-1990s has further explored the validity of the test in diverse settings such as personnel screening (Butcher, 1995); forensic assessment (Megargee, 2009); and test correlates with outpatients (Graham, 2000). Several studies have explored the use of MMPI-2-based personality descriptions in providing test feedback to psychotherapy clients. This research has shown that providing psychological test feedback in treatment increases the effectiveness of treatment (Finn, 1966; Finn and Tonsager, 1992; Newman and Greenway, 1997).

The MMPI-2 is also widely used as a cross-cultural research technique to study psychopathology across cultures. The MMPI-2 items and scales have shown remarkable resilience when used in other languages and cultures (Butcher, 1996), and computer-based interpretation of the MMPI-2 has been shown to be highly effective in describing clinical patients in other cultures (Butcher et al., 2009).

Conclusion

The MMPI-2 is the most widely used and most versatile clinical personality instrument that clinical psychologists have available. It is a self-report personality questionnaire that provides the test user with scores on a number of scales that address important clinical problem areas. In addition the MMPI-2 provides mental health professionals with information that allows them to appraise the client's willingness and frankness in the appraisal – key information about the client's response attitudes that allows for a determination of the credibility of the client's self-report. Once cooperation in the assessment is assured, the MMPI-2 clinical measures can be effective in delineating the mental health symptoms, personality traits, and special problems that the client is likely to be experiencing.

Minorities

Richard T Schaefer, DePaul University, Chicago, IL, USA

© 2015 Elsevier Ltd. All rights reserved.

This article is a revision of the previous edition article by Z. Layton-Henry, volume 14, pp. 9894–9898, © 2001, Elsevier Ltd.

Abstract

Minorities are subordinate groups whose members have significantly less control or power over their own lives than do the members of a dominant or majority group. In sociology, *minority* means the same as *subordinate*, and *dominant* is used interchangeably with *majority*. A minority group has five properties: unequal treatment, distinguishing physical or cultural traits, involuntary membership, awareness of subordination, and in-group marriage. Minority groups typically emerge through migration, annexation, and colonialism. The social consequences for minorities include extermination, expulsion, secession, segregation, fusion, and assimilation. Pluralism offers an alternative to complete societal dominance over minorities. Primarily through occupying an economic niche as self-employed entrepreneurs, middleman minorities provide desired services and sometimes products of use to both the majority and other minorities. Most typically, the term 'minorities' has been used to describe racial, ethnic or national, and religious minorities residing in a nation-state with a clearly defined majority (dominant) group. And also to writers such as youth or elderly, people with disabilities, exconvicts or exprisoners, and people with mental illnesses, people who are not solely heterosexual, and women to name a few.

Minorities have been the focus of study by social scientists for generations and the use of the term have a long history both in scholarship and in public discourse. Minorities are subordinate groups whose members have significantly less control or power over their own lives than do the members of a dominant or majority group. In sociology, *minority* means the same as *subordinate*, and *dominant* is used interchangeably with *majority*.

Minorities are therefore about unequal access to power and not necessarily a factor of sheer size and are being outnumbered by some other group or groups. Being superior in numbers does not guarantee a group control over its destiny and ensure majority status. Most dramatically in apartheid South Africa, Black Africans, Coloreds, and Asian Indians collectively outnumbered Whites by a ratio of 10:1, but were still very much subject to the control of the political and economic dominance of Afrikaners and English-speaking Whites. The economic legacy of apartheid rule from 1948 through 1994 is evident in the relative poverty rates in 2010 – 47% for black Africans and 0.5% for white South Africans (Kane-Berman, 2011: 312).

Similarly, in 1920, the majority of people in Mississippi and South Carolina were African-Americans. Yet African-Americans did not have as much control over their lives as Whites, let alone control of the states of Mississippi and South Carolina. Throughout the United States, today are counties or neighborhoods in which the majority of people are African-American, Native American, or Hispanic, but white Americans are the dominant force. Nationally in the United States, about 51% of the population is female, but males still dominate positions of authority and wealth well beyond their numbers.

While minorities may be defined by significantly less power as a group, that does not mean minorities are not without recourse. As we will note later, individual minority-group members may choose to immigrate as in the case of Jews to Israel. In addition, subjugated minorities may mobilize to confront the dominant majority as are Roman Catholics in Northern Ireland, Muslims in India, and Palestinians in Israel.

Confronted with evidence that a particular minority is subordinate to the majority, some people respond, "Why not? After all, the majority rules." However, the subordination of a minority involves more than its inability to rule over society. A member of a subordinate or minority group experiences a narrowing of life's opportunities – for success, education, wealth, the pursuit of happiness – that goes beyond any personal shortcoming he or she may have. A minority group does not share in proportion to its numbers what a given society, such as the United States, defines as valuable.

Characteristics of a Minority

A minority or subordinate group has five characteristics: unequal treatment, distinguishing physical or cultural traits, involuntary membership, awareness of subordination, and in-group marriage (Wagley and Harris, 1958).

1. Members of a minority experience unequal treatment and have less power over their lives than members of a dominant group have over theirs. Prejudice, discrimination, segregation, and even extermination create and maintain this social inequality.

The degree to which minority groups experience these disabling mechanisms, of course, varies with each group, and varies with the same group over time. The discrimination that black Americans encounter in the twenty-first century, although not as severe as under slavery, has still been discriminatory. To attempt to rank levels of discrimination by severity is difficult, and probably foolish. What constitute the worst denial of fights: the enslavement of black Africans, the decimation of tribal Indians by the United States Cavalry, or the placement of more than 110 000 Japanese Americans in relocation camps during World War II? Little is gained by ranking such injustices.

2. Members of a minority group share physical or cultural characteristics that distinguish them from the dominant

group, such as skin color or language. Each society has its own arbitrary standard for determining which characteristics are most important in defining dominant and minority groups.

By defining a group as a minority invoking certain physical traits, society isolates them from the dominant group, which encourages the development of certain cultural patterns unique to the minority.

3. Membership in a dominant or minority group is not voluntary; People are born into the group. A person does not choose to be an African-American or white.

Religious minorities may appear to be an exception to this property, but relatively speaking religion is largely passed on from parents to children. Conversion to a given faith does occur but those around them see often converts a bit differently whether inside the chosen faith or not.

4. Minority-group members have a strong sense of group solidarity. William Graham Sumner, writing in 1906, noted that people make distinctions between members of their own group (the in-group) and everyone else (the out-group). When a group is the object of long-term prejudice and discrimination, the feeling of 'us versus them' often becomes intense. Consequently, minority-group members develop an *esprit de corps*, a sense of 'I am one of them.'
5. Members of a minority generally marry others from the same group. A member of a dominant group often is unwilling to join a supposedly inferior minority by marrying one of its members. In addition, the minority group's sense of solidarity encourages marriage within the group and discourages marriage to outsiders.

In-group marriage, whether within a minority group or a majority group, is referred to as endogamy. The opposite, marrying out of one's own group, is exogamy. Even as recently as 2008, only 14.4% of all marriages by black men were with whites, and only 6.5% of all black women's marriages were with whites (Qian and Lichter, 2011).

The tendency of minority-group people to marry fellow group member is not an accident. The dominant group often has little respect on minority people and scorns those among the majority who, as they see it, lower themselves to marry someone of another group. Often, laws making intergroup marriages illegal buttress this scorn. For example when Barack Obama's parents married in Hawaii in 1961, the marriage between the white American Ann Dunham and the black Kenyan Barack Obama, Sr would not have been legal at the time in 22 states. Consequently, in-group marriage for minority people is not always due to choice, but can be a necessity as the majority refuses to form out-group marriages. Subordinate-group people may choose to marry among themselves in order to preserve their cultural heritage or in sincere feelings that marriage with a member of the dominant group would lead to personal unhappiness.

Emergence of Minority-Group Status

Minority groups typically emerge or, in some respects, disappear through a process that may occur in a very short period or over a series of generations. Three situations are likely to lead to the formation of a subordinate-group and dominant-group relationship. A subordinate group emerges through (1) migration, (2) annexation, and (3) colonialism.

Migration

People who immigrate to a new country often find themselves a minority in that new country. Cultural or physical traits or religious affiliation may set the immigrant apart from the dominant group. Immigration from Europe, Asia, and Latin America has been a powerful force in shaping the fabric of life in the United States.

Although people may immigrate because they want to, leaving the home country is not always voluntary. Conflict or war has displaced people throughout human history. In the twentieth century, we have seen huge population movements caused by two world wars; revolutions in Spain, Hungary, and Cuba; the partition of British India; conflicts in Southeast Asia, Korea, and Central America; and the confrontation between Arabs and Israelis. Environmental factors such as drought and floods have also been the source of migration from one's homeland.

In all types of geographical mobility, two sets of forces operate: *push factors* and *pull factors*. Push factors discourage a person from remaining where he or she lives. Religious persecution and economic factors such as dissatisfaction with employment opportunities are possible push factors. Pull factors, such as a better standard of living, friends and relatives who have already emigrated, and a promised job, attract an immigrant to a particular country.

While generally we think of migration as a voluntary process, much of the population transfer that has occurred in the world has been involuntary. The forced movement of people into another society guarantees a subordinate role. Involuntary migration is no longer common; although enslavement has a long history, all industrialized societies today prohibit such practices. Of course, many contemporary societies, including the United States, bear today the legacy of slavery.

Annexation

Nations, particularly during wars or as a result of war, incorporate or attach land. This new land is *contiguous* to the nation, as in the German annexation of Austria and Czechoslovakia in 1938 and 1939, respectively, and in the Louisiana Purchase of 1803. The Treaty of Guadalupe Hidalgo that ended the Mexican–American War in 1848 gave California, Utah, Nevada, most of New Mexico, and parts of Arizona, Wyoming, and Colorado to the United States. The indigenous peoples in some of this huge territory were dominant in their society one day, only to become minority-group members the next.

When annexation occurs, the dominant power generally suppresses the language and culture of the minority. Such was the practice of Russia in the immediate post-World War II era with the Ukrainians and Poles, and of Prussia with the Poles. Minorities try to maintain their cultural integrity despite annexation. Poles inhabited an area divided into territories ruled by three countries but maintained their own culture across political boundaries.

Colonialism

Colonialism has been the most frequent way for one group of people to dominate another. Colonialism is the maintenance of political, social, economic, and cultural domination over people by a foreign power for an extended period (W. Bell, 1991). Colonialism is rule by outsiders but, unlike annexation, does not involve actual incorporation into the dominant people's nation. The long control exercised by the British Empire over much of North America, parts of Africa, and India is an example of colonial domination.

Colonialism has often led indigenous people, such as tribal groups, to become a minority in an area they once were the majority (dominant) group. Examples of this process include the Maori of New Zealand, the First Nation people of Canada, and the Hawaiians of Hawaii. Societies gain power over a foreign land through military strength, sophisticated political organization, and the massive use of investment capital. The extent of power may also vary according to the dominant group's scope of settlement in the colonial land. Relations between the colonial nation and the colonized people are similar to those between a dominant group and exploited subordinate groups. The colonial subjects are generally limited to menial jobs and the wages from their labor. The natural resources of their land benefit the members of the ruling class.

Colonialism is domination by outsiders. Relations between the colonizer and the colony are similar to those between the dominant and subordinate peoples within the same country. This distinctive pattern of oppression is called internal colonialism. Among other cases, it has been applied to the plight of blacks in the United States and Mexican Indians in Mexico, who are colonial peoples in their own country. Internal colonialism covers more than simple economic oppression. Nationalist movements in African colonies struggled to achieve political as well as economic independence from Europeans. Similarly, African-Americans also call themselves nationalists in trying to gain more autonomy over their lives (Blauner, 1969, 1972).

Consequences of Minority-Group Status

There are several consequences for minorities of subordinate status. These differ in their degree of harshness, ranging from physical annihilation to absorption into the dominant group. In this section, we will examine six consequences of minority status: (1) extermination, (2) expulsion, (3) secession, (4) segregation, (5) fusion, and (6) assimilation. Finally, we consider pluralism that offers an alternative to complete societal dominance over minorities.

Extermination

The most extreme way of dealing with a subordinate group is to eliminate it. Today, the term genocide is used to describe the deliberate, systematic killing of an entire people or nation. This term is frequently used in reference to the Holocaust – Nazi Germany's extermination of 12 million European Jews and other ethnic minorities during World War II. More recently, the term ethnic cleansing was introduced into the world's vocabulary as ethnic Serbs instituted a policy intended to 'cleanse' – eliminate – Muslims from parts of Bosnia. Again in 1994, a genocidal war between the Hutu and Tutsi people in Rwanda left 300 000 school-age children orphaned.

Expulsion

Dominant groups may choose to force a specific subordinate group to leave certain areas or even vacate a country. Expulsion is therefore another extreme consequence of minority-group status. European colonial powers in North America and eventually the US government itself drove virtually all Native Americans out of their tribal lands into unfamiliar territory.

More recently, beginning in 2009, France expelled over 10 000 ethnic Roma (or Gypsies), forcing their return to their home countries of Bulgaria and Romania. This appeared to violate the European Union's (EU) ban against targeting ethnic groups as well as Europe's policy of 'freedom of movement.' In 2011, the EU withdrew its threat of legal action against France when the government said it would no longer expel Roma in particular but only those living in 'illegal camps,' which many observers felt was only a technical way for the country to get around long-standing human rights policies (Schaefer and Zellner, 2011).

Secession

A group ceases to be a subordinate group when it secedes to form a new nation or moves to an already established nation where it becomes dominant. After Great Britain withdrew from Palestine, Jewish people achieved a dominant position in 1948, attracting Jews from throughout the world to the new state of Israel. In a similar fashion, Pakistan was created in 1947 when India was partitioned. The predominantly Muslim areas in the north became Pakistan, making India predominantly Hindu. Throughout this century, minorities have repudiated dominant customs. In this spirit, the Estonian, Latvian, Lithuanian, and Armenian peoples, for example, not content to be merely tolerated by the majority, all seceded to form independent states following the demise of the Soviet Union in 1991.

Some African-Americans have called for secession. Suggestions dating back to the early 1700s supported the return of blacks to Africa as a solution to racial problems. The settlement target of the American Colonization Society was Liberia, but proposals were also advanced to establish settlements of freed slaves in Canada, Haiti, South America, and the western United States. Territorial separatism and the emigrationist ideology were recurrent and interrelated themes among African-Americans from the late nineteenth century well into the 1980s. The black Muslims, or Nation of Islam, once expressed the desire for complete separation in their own state or territory within the present borders of the United States. Although a secession of blacks from the United States has not taken place, it has been considered and even proposed in the past.

Segregation

Segregation refers to the physical separation of two groups in residence, workplace, and social functions. Generally, the dominant group imposes segregation on a subordinate group.

Segregation is rarely complete, however, intergroup contact inevitably occurs even in the most segregated societies.

The extent of racial and ethnic isolation globally and historically is staggering. Carl Nightingale (2012) observes that 'city splitting' took place in the past as the British East India Company, split Calcutta into 'White Town' and 'Black Town.' In Germany today, they speak of *Ghettoisierung* (or 'ghettoization') as concentrations of Turkish immigrants are emerging. Social scientists in Sweden have used the segregation index to document the isolation of Greek, Chilean, and Turkish immigrants from the rest of the population. Segregation is present in virtually all multiracial societies (Massey, 2012).

The focus on metropolitan areas should not lead one to overlook the continuing legally sanctioned segregation in rural areas as in the placement of Native Americans on reservations. Although the majority of our nation's first inhabitants do live outside these tribal areas, the reservations play a prominent role in the identity of Native Americans. They face the difficult choice that, while it is easier to maintain tribal identity on the reservation, economic and educational opportunities are more limited in these areas segregated from the rest of society.

Fusion

Fusion describes the result when a minority and a majority group combine to form a new group. This combining can be expressed as $A + B + C \rightarrow D$, where A, B, and C represent the groups present in a society, and D signifies the result, a cultural racial group unlike any of the initial groups. Theoretically, fusion does not require intermarriage, but it is very similar to amalgamation or the cultural and physical synthesis of various groups into a new people. In everyday speech, the words *fusion* and *amalgamation* are rarely used, but the concept is expressed in the notion of a human melting pot, in which diverse racial or ethnic groups form a new creation, a new cultural entity (Newman, 1973).

As noted earlier, when identifying the properties of minorities, there is only modest evidence in the United States of a fusion of races. Racial intermarriage has been increasing, and the number of interracial couples immigrating to the United States has also grown. This growth of the so-called 'mixed marriages' can be seen in the growing presence of children of biracial or multiracial parentage, leading the Bureau of the Census to allow individuals to indicate more than one race in the decennial censuses. Most people did select one racial category in Census 2000 and again in 2010. Overall, approximately 9 million people, or 2.9% of the total population, selected two or more racial groups in 2010. Some self-identified biracial or multiracial people see themselves as a minority distinct from those identifying a single race or ethnic ancestry (Humes et al., 2011).

Assimilation

Assimilation is the process by which a subordinate individual or group takes on the characteristics of the dominant group and is eventually accepted as part of that group. Assimilation is a majority ideology in which $A + B + C \rightarrow A$. The majority (A) dominates in such a way that the minorities (B and C) become indistinguishable from the dominant group. Assimilation dictates conformity to the dominant group, regardless of how many racial, ethnic, or religious groups are involved (Gordon, 1964; Newman, 1973: 53).

To be complete, assimilation must entail an active effort by the minority-group individual to shed all distinguishing actions and beliefs and the total, unqualified acceptance of that individual by the dominant society. In the United States, dominant white society encourages assimilation. The assimilation perspective tends to devalue alien culture and to treasure the dominant. For example, assimilation assumes that whatever is admirable among blacks was adapted from whites and that whatever is bad is inherently black. The assimilation solution to black–white conflict is the development of a consensus around white American values.

Assimilation is difficult for minorities. The individual must forsake his or her cultural tradition to become part of a different, often antagonistic, culture. Members of the subordinate group who choose not to assimilate look on those who do as deserters. Many Hindus in India complained of their compatriots who copied the traditions and customs of the British. Those who assimilate must totally break with the past. Australian Aborigines who become part of dominant society conceal their origin by ignoring darker-skinned relatives, including their immediate family. As one assimilated Aborigine explained, "Why should I have anything to do with them? I haven't anything in common with them, and I don't even like most of them" (Berndt and Berndt, 1951: 264). These conflicting demands leave an individual torn between two value systems.

Pluralism

The alternative to divisive relationships between the majority and the minority is pluralism. Pluralism implies that various groups in a society have mutual respect for one another's culture, a respect that allows minorities to express their own culture without suffering prejudice or hostility. Whereas the assimilationist or integrationist seeks the elimination of ethnic boundaries, the pluralist believes in maintaining many of them.

There are limits to cultural freedom. A Romanian immigrant to the United States could not expect to avoid learning English and still move up the occupational ladder. To survive, a society must have a consensus among its members on basic ideals, values, and beliefs. Nevertheless, there is still plenty of room for variety. Earlier, fusion was described as $A + B + C \rightarrow D$ and assimilation as $A + B + C \rightarrow A$. Using this same scheme, we can think of pluralism as $A + B + C \rightarrow A + B + C$, where groups coexist in one society (Newman, 1973).

In the United States, cultural pluralism is more an ideal than a reality. Although there are vestiges of cultural pluralism – in the various ethnic neighborhoods in major cities, for instance – the rule has been for subordinate groups to assimilate. Yet as the minority becomes the numerical majority, the ability to live out one's identity becomes a bit easier. African-Americans, Hispanics, and Asian Americans already outnumber whites in nine of the ten largest cities. The trend is toward even greater diversity. Nonetheless, the cost of cultural integrity throughout the nation's history has been high. The various Native American tribes have succeeded to a large extent in

maintaining their heritage, but the price has been bare subsistence on federal reservations.

The most visible controversy about pluralism for ethnic or language minorities is the debate surrounding bilingualism. Bilingualism is the use of two or more languages in places of work or education, with each language being treated as equally legitimate. The passionate debate under way in the United States over bilingualism often acknowledges the large number of people who do not speak English at home. In education, bilingualism has seemed to be one way of helping millions of minority people, who want to learn English to function more efficiently within the United States.

Middleman Minorities

Sociologists and economists have described a subgroup of minorities called middleman minorities. Subject to discrimination and inequality, such middleman minorities do not experience extreme discrimination. Primarily through occupying an economic niche as self-employed entrepreneurs, they provide desired services and sometimes products of use to both the majority and other minorities. Typically, they remain apart from larger industries such as manufacturing and agriculture. More specifically, typical enterprisers include barbers, restaurant owners, tailors, launderers, and jewelers. The enterprises tend to be relatively transportable or easily liquidated, since reprisals from the dominant group are always a possibility.

Based on a dominant–subordinate stratification system, middleman minorities occupy an intermediate rather than low-status position. At different times, middleman included Jews throughout Europe – even at times when the discrimination against them was at their peak such as during World War II they still had great success in some parts of Europe, Chinese throughout Southeast Asia, and Indians in East Africa (Bonacich, 1973; Blalock, 1967).

Broadening the Use of Minorities

Most typically 'minorities' has been used to describe racial, ethnic or national, and religious minorities residing in a nation-state with a clearly defined majority (dominant) group. Since the subjugation of such minorities is well known, writers, both scholarly and otherwise, have found it useful to use the term minorities to describe much different groups. In this manner to say 'minority,' serves as a shorthand to describe subordination, disadvantage, and clearly defined boundaries distinguishing them from the dominant group. The notion of minority in this broader sense has been applied to age groups such as youth or elderly, people with disabilities, exconvicts or exprisoners, and people with mental illnesses to name a few (Farley, 2005; Spiegel and Keith-Spiegel, 1973).

A significant minority that has a visible public presence recently in the political sphere of social policy are those people who seem to stand outside those with a heterosexual orientation. A generation ago, homosexuals or gay and lesbians seem to be a sufficient descriptor. But in recent years, the general public consciousness has been alerted to the complexity of the expression of human sexuality. Hence, minorities can be said to be defined by those who are bisexual or transgendered. Continuing the recognition of the complexity of sexual orientation, some question the use of term bisexual as only serving to reinforce the binary rubric of sexuality and thus contended that a more appropriate term is pansexual to describe people who are sexually attracted to people of all gender identities and biological sexes (Cavendish, 2010).

Women as a Minority

The most common analogy about minorities beyond racial, ethnic, and religious groups used in the social sciences is the similarity between the status of African-Americans and that of women. Blacks are considered a minority group, but one asks, How can women of all groups be so similar in condition? We recognize some similarities in recent history; for example, an entire generation has observed and participated in both the civil rights movement and the women's movement. A background of suffrage campaigns, demonstrations, sit-ins, lengthy court battles, and self-help groups are common to the movement for equal rights for both women and African-Americans. But similarities were recognized long before the recent protests against inequality. In *An American Dilemma*, the famous study of race relations in the United States, Gunnar Myrdal (1944) observed that a parallel to the blacks' role in society was found among women. Others, like Helen Mayer Hacker (1951, 1974), later elaborated on the similarities.

Women are an oppressed group; they are a social minority in the United States and throughout Western society. Men dominate in influence, prestige, and wealth. Women do occupy positions of power, but those who do are the exception, as evidenced by newspaper accounts that declare 'she is the first woman' or 'the only female' to be in a particular position.

Many people, men and women, find it difficult to conceptualize women as a minority. After all, women do not live in ghettos. They no longer have to attend inferior schools. They freely interact and live with their alleged oppressors, men. How, then, are they a minority? Considering the five properties of a minority group, women do experience unequal treatment. Although they are not segregated by residence, they are victims of prejudice and discrimination. Women have physical and cultural characteristics that distinguish them from the dominant group (men). Membership in the subordinate group is involuntary. Through the rise of contemporary feminism, women have become increasingly aware of their subordinate status and have developed a greater sense of group solidarity. While women are not forced to marry endogamous; yet many women feel that their subordinate status is most irrevocably defined within marriage.

Utility of Minority as a Descriptor

Minority is a term that emerged from use of scholars into public discourse as a way to describe inequality between groups of people and not necessarily between specific individuals. Minimally, minority in the United States is taken to mean

minority racial and ethnic groups with federal programs that target 'minorities' such as the Small Business Administration. In this use, minority refers to African-Americans, Asian Americans, Pacific Islanders, American Indians, and Hispanics.

Beyond this grouping, minority includes other ethnic groups such as Jewish Americans, religious minorities such as Muslims in the American context, women, as well as a variety of groups that are disadvantaged in contemporary society. While some decry this broadening of the definition and others question identifying as a minority as some sort of personal weakness, the term minority seems entrenched in the public and academic nomenclature for some time.

Miracles, Cultural Logic of

Paolo Parigi, Stanford University, Stanford, CA, USA

© 2015 Elsevier Ltd. All rights reserved.

Abstract

Miracles are not a residual category of science, nor are they the result of ignorance. For millions of people, miracles continue to play an important role in modern life. This article explores the resilience of miracles by considering two key factors: (1) the relationship between the institutions of religion and science, and (2) the power of miracles to mobilize dedicated constituents. The article argues that taken together, these two factors turn miracles into social facts. In the final part of the article, modern sainthood is used as an example to illustrate how the Catholic Church negotiated its relationship with science at the dawn of modernity and how miracles continue to have the power to mobilize people. Some segments of this article were adapted from my book, *The Rationalization of Miracles*, Cambridge University Press.

Although many people might assume that a miracle is merely a residual category of event, destined to be marginalized by such processes of modernity as secularization and scientific progress, for millions of people miracles remain a key element of modern life. Miracles continue to occur abundantly around the world despite advancements in scientific understanding and a decrease in church attendance. Durkheim famously defined a social fact as a "way of acting, fixed or not, capable of exercising on the individual an influence, or an external constraint" (1969: p. 26); social facts are the 'things' that social scientists study. The resilience of supernatural events is important for sociologists and social scientists more broadly because it highlights a core characteristic of miracles: whatever else they may be, they are undeniably social facts.

How did miracles survive the challenges of modernity and manage to become a social fact? One key to this question is the struggle between religious institutions, like Christian churches, and the scientific community over control of the category of miracles and the authority to sanction (or debunk) miraculous claims. Another key is an understanding of the capacity of miracles to mobilize people in a common cause. Indeed, this mobilizing power is the difference between a miracle and a personal fantasy.

Before examining in greater detail how these two factors combine to make miracles a social fact, I offer a definition of miracle as any event that defies common expectations and for which a readily available mental frame exists that denies or eliminates the role of randomness as a cause for the event. A social world without miracles has always been possible, now as 500 years ago. It is a rational world ruled by stochastic processes where random events occur as a matter of routine. The fact that many people do not see the world in this way tells us a lot about our modern societies and, perhaps, about our collective expectations and fears as human beings.

After discussing how the scientific community, religious institutions, and activists all contribute in turning miracles into social facts (see Section The Relationship between Science and Religion and the Creation of New Knowledge), I will examine in greater detail the exemplary case of modern Catholic saints. In particular, I will reconstruct the historical transformation of sainthood at the hands of the Catholic Church during the seventeenth century and how such transformation made miracles compatible with modernity (see Section An Extended Example: Modern Sainthood). Because of the Church's overt attempts to use rules to regulate the production of miracles, modern sainthood is an ideal typical case for studying miracles as social facts in other Christian religions too.

The Relationship between Science and Religion and the Creation of New Knowledge

In the Christian religions, most miracles are health related, thereby making the relationship between religious institutions and medical scientists the focus point of my analysis. A metaphor known as Zeno's Paradox could help illustrate this relationship. The Greek hero Achilles is racing against a turtle. Achilles is 10 times faster than the turtle, so he gives the turtle a head start of 10 spatial units. Will Achilles ever reach the turtle? If the distance the two have to run is infinite, the answer is no, because the turtle will always be 10 units ahead of Achilles, no matter how infinitesimal the units are. If we subscribe to the view that modernity has transformed death from a fundamental aspect of human's life (regulated by rituals and traditions) into an undesirable and 'hidden' outcome of science and medicine, then religious institutions and medical scientists become similar to the turtle and Achilles respectively, running the infinite distance of modern life. Miracles will always occur in the space of what is unpredictable.

If Zeno's Paradox provides a key for understanding why the supernatural remains part of modernity it does not explain 'how' such a process developed in time – the institutions and actors involved in the production of miracles and the historical circumstances that created the modern field of religion. In this article, I argue that the current relationship between modern religious institutions and science (medicine in particular) can be recast as one of control over a boundary: the boundary that separates the possible from the impossible. Modern science failed to displace miracles because Christian churches defended this boundary, claiming authority on the impossible side of the

division. While before the modern period, religion dictated what was to be considered 'officially' a miracle (an event that imitated the life or actions of Jesus, for instance see Vauchez, 2000; Boesch-Gajano, 1999), strong enforcement of the possible/impossible division became the cornerstone on which miracles could continue to occur in the modern period, without any need to define the content of the impossible. Indeed the priest (or pastor) and the scientist are commonly perceived as representatives of opposite and distant worlds. One world, that of science, is predicated on openness, experiments, and results; the other world, that of religion, is predicated on mysteries and dogmas.

Nevertheless, several social scientists have shown how categories evolve over time and boundaries become porous. Hannan and Freeman, for instance, considered several social processes, such as personnel turnover and technical errors, which usually lead to the blending of opposite categories (1989). Rao, Monin, and Durand considered a successful case of such blending in the realm of French gastronomy (2005). Indeed one could interpret certain aspects of positivism during the eighteenth century – the intuitions that led Auguste Comte to invent the word 'sociology,' for example, or Saint Simon's vision of a technocratic society (2009) – as a blending between science and religion. Had such a blending been successful, my argument suggests, miracles would have disappeared from the landscape of religious life. Why did the boundary of the possible/impossible remain salient during modernity?

One reason that this boundary did not become porous at the end of the nineteenth century was that religious institutions throughout the Christian world continued to train their own personnel quite separately from the state-controlled training of scientists and other professionals. Maintaining control over the training of the clergy was (and is!) important because it produced a specific knowledge about the realm of the impossible that justified the existence of a rigid boundary. In his historical analysis of the relationship between mental illness and civilization, Michel Foucault argued that once the mentally ill started to be moved into institutions, they fell under the scrutiny of a power that began distinguishing between different types of psychological malady – alcoholism, depression, etc. Different types of mental illness became the objects of analysis of a new discipline, psychology (Foucault, 2001). Similarly, different types of impossible events came under the scrutiny of the clergy, which transformed some of them into miracles. As with the case of psychology, power – in this case, the power of religious institutions expressed through the training of their personnel – generated knowledge – in this case, a knowledge of the impossible.

No other church extended this process of knowledge creation further than the Catholic Church. In the aftermath of the Protestant Schism, Rome embarked on a deep reorganization of its centennial structure and created a specific commission to investigate miracles performed by candidates for sainthood and by objects such as statues, icons, and paintings. While the latter part of this article will provide more historical details about this fascinating and not widely known period of Church history, it is worth pointing out that Rome's strategy as ultimate arbiter of the impossible did more than defend a boundary line. In effect, the Catholic Church achieved control over the boundary. This is illustrated by the simple fact that Catholics throughout the world consider true miracles not just those events that defy scientific expectations but also those that have received approval from the Pope. That is, for Catholics, not every impossible event is *ipso facto* a miracle.

In light of all of this, the relationship between modern religious institutions and science is not one of progressive domination of the latter over the former. This simplistic perspective, perhaps better captured with Francis Bacon's sentence that "knowledge is power," ignores that science and religion are two separate and autonomous systems of beliefs, practices, values, and rules – and that power, too, is capable of creating knowledge. Only by restoring the complexity of the social world in which scientists and priests live together, it is possible to start understanding the resilience of miracles.

The Mobilizing Power of Miracles

In the modern world, most supernatural events take place privately between a single worshipper and his or her deity. This type of miracle is private in the sense that it does not involve others beyond the individual and, potentially, his or her immediate family. Private miracles do not have mobilizing power and are a matter of personal beliefs, i.e., they are not social facts. A subset of miracles are, however, public, in the sense that they occur at pilgrimage destinations or are used for establishing someone's sanctity by the Catholic Church. Still other times, miracles are public because they occur in public spaces in front of several people. Many social scientists tend to think that public miracles are the result of crowd behavior or are spontaneous eruptions of faith and are, in this sense, comparable to private miracles. This way of thinking about miracles has led social scientists to in large part ignore them as objects of study. However, in reality, public miracles more closely resemble mobilizing events of contemporary social movements, and are worth studying as organized expressions of religious activism.

Indeed, behind each public miracle – be that a healing performed by a powerful relic of a soon-to-be-saint or the crying of a religious icon in front of hundreds of worshippers – there is always a group of activists that first catalyzed the conditions for the occurrence of the miracle and then organized the local support generated by the miracle so that more miracles could occur. This group of activists could be made of early acolytes of a recently deceased candidate for canonization, or it might comprise the clergy of a potential pilgrimage destination. Regardless, activists benefit directly from the occurrence of the miracle and stand to further benefit from the occurrence of more supernatural events.

This is not to suggest that the religious motivations of activists are of secondary importance. Rather, it serves as a reminder that the mobilization of a community via miracles also produces worldly advantages for some people. Pilgrimage is one example. A steady stream of pilgrims generates revenue that can be channeled either to a local church or a religious order. But while the economics of a miracle can be a boon for activists, they do not merely reap the reward. The activists' efforts to organize the miracle are actually essential for the miracle to exist as a social fact, and for a subtle reason – the

participation of activists makes public miracles compatible with a cultural and social environment dominated by skepticism toward supernatural events.

Religious activists catalyze the occurrence of miracles through the use of ritual. In the case of public miracles performed by a Catholic saint, for instance, they occur via the intercession of a relic that it is usually in the control of the activists. The ritual performs the function of expelling chance from the equation and ensuring that everything that happens as a result of it is the result of God's will. The ritual creates a frame that makes an unpredictable event predictable, and therefore reproducible. By showing that the event obeys God's laws, the ritual creates a legitimate suspension of natural laws (or of medical knowledge) so that, for example, the places where these types of miracles occur are *de facto* places for supernatural activity on Earth.

Using rituals in order to make miracles align with modernity represents an extension of Max Weber's thesis on the rationalization of religion (1922). The mobilizing power of miracles shows that, in fact, the rationalization of religious beliefs did not mean only the exclusion of magic from religion, i.e., Puritanism. The path traveled in Northern Europe to make Christian religious beliefs compatible with modernity was just one possible solution to the tensions created by scientific progress and medicine. Another solution was to leave some magic into the religious core of Christianity. What this article argues is that the rationalization of religion is better seen as a historical and institutional process that involves activists legitimizing and structuring what can be considered genuinely supernatural, i.e., a miracle that occurred as the effect of a ritual (the cause), according to their own interests and ideology.

An Extended Example: Modern Sainthood

Miracles are part and parcel of the modern world and are a key aspect of Catholicism. Sainthood would not be *necessary* without miracles, i.e., without the widespread belief in miraculous events and the cultural understanding that such events are the work of holy individuals after their death (*postmortem*), because they sit in paradise and are thus able to intercede for us with God. The story of modern sainthood shows to the maximum extent how the Church constructed a specific knowledge of the impossible in contrast to the discoveries of science, and how religious supporters of future candidates for sainthood used (public) miracles to mobilize local communities in support of the canonization of their leaders. The institutional process that made it possible for modern saints to continue performing (public) miracles thus serves as an illustration of how social facts are created. In what follows, I will provide some historical detail of the reorganization of the Catholic Church in the aftermath of the Protestant schism. My attention will focus first on sainthood during the medieval period and then on the special commission that Rome created with the intention of reforming it.

Sainthood before the Protestant Schism

In the Middle Ages the ascetic, healing saints, as typified by Saint Francis of Assisi, were prevalent in Italy and had a long history going back to the late Roman Empire (Brown, 1981), while the noble kinship saints, such as Saint Louis, were dominant in France and were a more recent version of sainthood (Vauchez, 2000, 1989). For the most part, the popes canonized candidates that conformed to the Italian model of sainthood.

Models of sainthood did not vary only by region (Duby, 1980). Because the popes did not have complete control over matters of sainthood until the seventeenth century, Boesch-Gajano and Modica suggest distinguishing types of sanctity based on the authorities that certified them. *High* sainthood in this model coincides with official sainthood, one that received the approval of the pontiffs (2000). *Low* sainthood, on the other hand, refers to sanctity achieved through popular acclaim and certified by local authorities. The case of a dog worshipped as a saint in the village of Villars-les-Dombles in the Ain region of Southern France is a notorious example of this latter type of sanctity. The dog, Guinefort, was (incorrectly, it turned out) accused of having killed a baby and was thrown in a well and killed. After discovering the dog's innocence, the population of the village began to worship the dog, which from that point on (and up to the eighteenth century) was known as Saint Guinefort. Vauchez explains: "In the contrast to … harsh punishment and its patent injustice, popular piety was born. This popular emotion is the same which, transposed on the religious sphere, generated devotion. By virtue of a process that we can treat as a 'law of popular affectivity,' popular piety generates religious piety" (1989: p. 101).

Nevertheless, official sainthood did require the support of people, what the Church called the *Fama Sanctitatis*, in addition to papal approval of a candidate's sanctity. In the Middle Ages, the support a saint could attract was based largely on his miracles; hence, miracles were a vital instrument for gathering the popular support necessary for canonization. Organizing this support through the use of rituals was not that fundamental, however. Summarizing the field of sainthood before the Protestant schism we can say that while *low* saints had popular support, *high* saints had prestige.

During the reformation, Protestants attacked the Church's indulgence to popular devotion of the kind that produced the dog Saint Guinefort. At the same time, the great rate of scientific discoveries popularized via the printing press contributed to produce a shift in climate, whereby supernatural events began to be greeted with increasing skepticism. Thus, at the dawn of modernity, the Church was faced with the dual challenge of promoting its own version of sainthood while attracting popular support. To a certain degree, the two goals had the potential to undermine one another: allowing popular devotion was important in ensuring popular support, but allowing too great a variety of popular devotion would seem to prove skeptics right because it could potentially turn any popular mystery into a holy act. The establishment of a central commission to investigate claims to sainthood was part of the Church's effort to reshape the relationship between popularly perceived sainthood and its own official version.

But *how* did the new commission effect this reshaping? It took considerable organizational skill to steer the environment from one in which putative saints faced lax scrutiny and were proclaimed locally to one in which Rome asserted close control over sainthood, all the while maintaining popular support.

The Church risked alienating its followers in a period when the legitimacy of its dogma was much in question and when religious wars challenged the political authority of Rome.

The Special Commission for Investigating Miracles and Saints

Pope Sixtus V created the *Congregatio Sacrorum Rituum*, or Congregation of Sacred Rites, with the 22 January 1588 encyclical *Immensa Aeterni Dei*. The *Congregatio* was originally charged with organizing and moderating the Latin liturgy of the Church as well as investigating whether individuals who died with reputations of extreme holiness were indeed saints. The latter function quickly took precedence, so that the work of the *Congregatio* resembled more and more that of a tribunal that 'tried' candidates for sainthood after their deaths (Papa, 2001).

The establishment of the *Congregatio* was the culmination of a long process that began on 9 February 1993, at the Church of Saint John in Rome, when the pope officially sanctioned the worship of the bishop of Augsbourg, Saint Udalric. This was Rome's first documented canonization. Interestingly, the *bolla*, i.e., the Pontiff's communication, issued for the occasion described the 20 miracles that Udalric had performed. Similar canonization bulls listing miracles continue to be issued to this day (Papa, 1988).

Despite this early example, the Roman Curia and the papacy had very little control over granting the title of saint. Throughout the Middle Ages, Catholic Europe was divided in its devotion to a myriad of local saints. This state of affairs persisted even though, in order to prevent abuse of the title and to institute some consistency, Pope Alexander III officially took the power of canonization out of the hands of local bishops in 1170 with the decree *Audivimus, de Reliquiis et Veneratione Sanctorum*. But the decree was not enforced, partly because of the difficulty of controlling a territory as vast as Europe and partly because it made little organizational sense to risk alienating popular support. The practice of worshipping local saints continued.

However, in the new social landscape of the Counter-Reformation, the saints and their miracles were a matter of particular importance, and a subject about which Protestants and Catholics fought fiercely (Thomas, 1971). In this environment, Rome had a direct interest – for the sake of its own credibility – in assuring the quality of the people worshipped as saints. As Rome began to insist more strongly on the importance of its approval, local religious activists found an interest in securing Rome's recognition of their candidate, in order to enhance their local reputation. The two demands, one from the top and the other from the bottom, met in the procedures of the *Congregatio*, which transformed sainthood into a standardized legal procedure (Gotor, 2000, 2004).

The canonized sainthood that the *Congregatio* instituted was based on a series of trials in which witnesses were called to testify on the miracles and virtues of the candidate. Each trial was divided into sections, and witnesses were called for each. The sections were (1) the early life of the candidate; (2) the sanctity of the candidate in a broad sense; (3) the virtue of faith; (4) the virtue of hope; (5) the virtue of charity toward God; (6) the virtue of charity toward spiritual life; (7) the virtue of charity toward temporal life; (8) the virtue of prudence; (9) the virtue of justice; (10) the virtue of patience (only for French candidates); (11) the virtue of strength; (12) the virtue of the religious life, if the candidate belonged to a religious order; (13) the supernatural gifts of the candidate; (14) the *Fama Sanctitatis*, or saintly reputation of the candidate; (15) the death of the candidate; (17) the candidate's fame after death; and (18) the miracles.

Local church authorities opened the canonization procedure by collecting evidence on the recently deceased holy person and commissioning the writing of *vitae*, or biographies. This first phase was called the *Processo Ordinario*, because the authority that conducted the investigations was ordinary, or locally based. The evidence gathered in the *Processo Ordinario* was sent to the *Congregatio* in Rome, where it received its first scrutiny, based on the way the trial was conducted – whether all the necessary authorities were present, whether the depositions were sealed and the minutes recorded, etc. Approval in this phase meant that a new trial would be held, this time by the apostolic authorities; therefore the new trial was thus called the *Processo Apostolico*. The judges in this trial were all selected by Rome. If the *Congregatio* reached a positive opinion in the *Processo Apostolico*, it issued the *Lettere Remissoriali*, or permission to gather evidence on specific details (*in partibus*) of the candidate's life and the miracles he performed. Since many candidates were active in more than one parish during their lives, both the ordinary and apostolic trials were held in multiple locations, in effect multiplying the number of required trials (Veraja, 1988).

The trials *in partibus*, often called *Remissoriali*, were conducted by the Roman authorities. Until the decrees of the period 1634–42, the *Congregatio* entrusted a special commission, the *Uditori di Rota*, with the task of organizing most of the work related to these trials. The *Uditori di Rota*, of whom there were three, were the pope's trustworthy advisors. All of them held important positions in the Roman Curia; they were usually cardinals and they were often members of the *Congregatio*. Their predominance in the first decades of the life of the *Congregatio* shows that the pope intended to maintain close supervision over matters of sainthood (Papa, 2001). The *relatio*, or summary of the trials, that the *Uditori* wrote for the *Congregatio* and for the pope was the single most important document in a canonization process during this period. This summary of the life of the candidate was divided into two parts: the first addressing the virtues of the candidate, and the second his miracles. The miracles discussed in the *relatio* were a selection of all those collected during the trials.

The process of developing modern sainthood was a precarious one that required balancing conflicting interests. This meant that the *Congregatio* refined and changed its rules many times over the years between its founding and the reforms of the period 1634–42. At the beginning of the seventeenth century, the *Congregatio* instituted one of its first new rules by creating the title of *beato* (blessed). This title had existed informally since late antiquity, indicating a cult that the Roman authorities had approved for the purpose of local worship only. After the *Congregatio's* rule change, the title of blessed became in practice an intermediate step to sainthood. Local authorities carried out the investigations for the title, which allowed them to assert some autonomy from the Roman Curia. Thus, the institution of the title *blessed* mediated between Rome's desire to assume direct control over sainthood and the prerogatives of

local communities that had chosen their own saints for centuries (Gotor, 2004).

The reforms of 1634–42 introduced a new figure to the canonization process that drastically reduced the role of the cardinals of the *Congregatio* and completely replaced the *Uditori*. The *Promotore Fidei* – a 'devil's advocate' with respect to the candidate's position – was charged with the task of dismantling any false claims about the powers and virtues of the candidate. The *Promotore Fidei* was a lawyer entrusted with representing the interests of the Church on matters of sainthood, and he usually represented the Church several times during his career. The use of legal experts on religious matters had been a long-standing tradition in the Church, but the extent of their involvement in canonization procedures was one of *Congregatio*'s many institutional innovations. The first attorney nominated to defend the interests of Rome during a canonization trial was Giovanni Giacomo Nerotti in the case of Raymond de Penafort, a Spanish saint worshipped since the thirteenth century. However, Nerotti's task remained confined to the traditional role of the Curia's attorney – i.e., establishing that local trials followed proper procedures. Nerotti and his counterpart on de Penafort's behalf, the Dominican priest Michele Llot, did not address the merits of de Penafort's purported miracles.

With the expansion of scientific and medical knowledge during the seventeenth century, the *Promotore*'s role also expanded beyond procedural supervision to resemble that of a defense attorney defending the integrity of the Church poking holes in the evidence offered by the prosecutor of the case, i.e., the lawyer for the candidate. This required the creation of a legal-theological framework for handling medical knowledge. With the *Promotore's* changing role came a new title – *Promotore Fidei*, or protector of the faith. While several documents from the first decades of the seventeenth century mention the new title, the job itself was not officially created until the reforms of 1634–42. Key to the *Promotore Fidei's* job was authoring opinions (*animadversiones*) about the candidate's miracles. These documents, which outlined the *Promotore*'s doubts about the miracles, would circulate among the members of the *Congregatio* and the pope.

In describing his 'doubts,' the *Promotore* used the best medical authority accessible to him in order to poke holes in the evidence collected about miracles by the candidate's attorney, the *Postulatore*. The *Promotore*, i.e., operated similarly to the devil's advocate and it is likely that it is this institutional arrangement that popularized the expression 'devil's advocate.' With time, the expertise the *Promotore* accumulated in the process of debating cases helped the *Congregatio* produce new and more refined knowledge about miracles. For example, it was in this period that the notion took hold that a true miracle required that healing must occur instantly and completely (Antonelli, 1962). The *Congregatio* incorporated this idea into an established classification of miracles by degrees that dated to Saint Augustine. This produced a new, more refined list of the characteristics of a true miracle; knowledge of and the ability to judge those characteristics belonged to the Church, not doctors. In this way, the *Congregatio* was able to create a legal framework to control the boundaries of the supernatural and to protect it from the potential further claims of medicine. The new institutional figure of the *Promotore* gave to the process of canonization its lasting form.

The Mobilizing Power of Miracles

Immediately after the candidate's departure for paradise (the *dies natalis*, in Church terminology), his acolytes were faced with the problem of how to ensure that their leader's message of religious reform could continue. In the absence of the deceased leader's personal charisma the leader's message would only continue to propagate if new activists were brought to the cause of the candidate's sanctity. The involvement of newcomers required that acolytes mobilize a community and this mobilization translated directly into creating the conditions for the occurrence of more miracles. However, since the candidate was not there in the flesh, the acolytes had to be careful to connect the occurrence of the supernatural event to the efforts of the candidate who, sitting close by God in paradise, was interceding for the sick person. Acolytes had to exercise skill in building, and controlling, the networks that generated miracles on behalf of their candidate (Parigi, 2012).

The days immediately after the candidate's death marked a special time in the community where the candidate and his acolytes had been active. It was during this period that the acolytes could potentially capitalize on their skills as activists, because opportunities for miracles multiplied in the days following the *dies natalis*. If the candidate were truly a saint, the general population expected to see *postmortem* miracles, which of course could only occur after the *dies natalis*. The days immediately after the candidate's death were also the time when it was the easiest to create relics of the saint, which would be the main vehicle of those *postmortem* miracles. Relics would prove the involvement of the candidate in *postmortem* miracles, and the candidate's acolytes would hope to control them in order build their network and create more miracles.

The public's interest in relics came from the deeply held belief that relics had healing powers. For instance, when friar Rainiero, a candidate for sainthood who lived in central Italy, died on 23 August 1589, his acolyte and fellow friar Egidio da Amelia testified that a mob rushed to the body that lay inside the church and began quite literally to tear him apart – taking his hair and pieces of his clothes and punching holes into his body so that tissues could be soaked in his blood (ASV 3238; 3241; ACS *Storico*, 223). A similar scene happened when friar Pasqual Baylon, another candidate that lived in the same period as Rainiero, died in Villa Real, Spain (ASV 3393). Egidio's testimony exemplifies the fact that public fervor was directed mostly toward pieces of the candidate's body, the most common kind of relics. It would be a grave mistake to think that only the lower strata of society believed in their power. Philip II, the king of Spain from 1556 to 1598, amassed a collection of more than 100 relics in the palace-monastery Escorial (Parigi, 2012).

But generally a mob did not tear the body of a candidate to pieces. The acolytes had direct access to relics, and so they were called upon to attend to the sick. Over time, a ritual developed. Upon arriving at the sick person's house, the acolyte would invite everyone present to pray, often instructing them to kneel and pray aloud together. During the prayer, the acolyte asked

his candidate for grace for the sick person and at this point usually took out one of the candidate's relics, which he applied to the invalid. The other people present would still be kneeling in prayer. The acolyte would then leave the scene and the other people would notice a sudden improvement in the invalid's condition. Immediately or within the span of a few days, the sick person would be perfectly healed, having become a 'saved.' (This describes most *postmortem* healings. It is not, however, what Church doctrine required of genuine miracles. As previously mentioned, the Church mandated an instantaneous healing that in reality seldom occurred.)

Successfully organizing public fervor into a community mobilization therefore meant maintaining strict control over the candidate's relics. Acolytes organized their control of the relics through the creation of the ritual healing. The ritual helped construct a predictable mental frame – based on popular beliefs about how nature and society worked – around (unpredictable) illnesses and thereby 'produced' healings. As an expression of a strict set of guidelines, a ritual reduced uncertainty by removing chance from the equation and instead offered evidence that all forces obeyed God's laws. A healing was a patterned process in time in which the behavior of each actor involved was symbolic (Turner, 1967). Acolytes catalyzed *postmortem* miracles through their role as performers of a ritual, at whose center stood the candidate or a piece of his body.

Successful acolytes were those who knitted a community together using miracles. This was not a simple task and required considerable organizational skills. The protosocial movement that acolytes organized would then become the main force supporting the canonization efforts. Why would acolytes want to secure the *Congregatio*'s approval? The simple answer is that they faced competition from other religious activists, and such competition created havoc in many local communities. For instance, a priest in a small village near Milan was exasperated by all the attention attracted by a crying image of the Virgin Mary in a nearby parish. During the trial held by the Church authority on the case, he told the judges explicitly that his constituency was diverting prayers and money to the other parish, creating problems for him and his Church (Sangalli, 1993). Competition was particularly fierce where supernatural results were perceived to be produced by a candidate's relics. For example, the internal organs of Filippo Neri (a candidate to sainthood that lived in the sixteenth century) were secretly taken from Rome and brought to Naples, where they ended up in the hands of a noblewoman (*Il primo processo*). Similarly, the head of Bernardino of Santa Lucia, another candidate to sainthood that lived in the same period, was stolen from the Franciscan Church in Agrigento, Italy, where the whole body lay exposed (ASV 2209). A list of such anecdotal examples could go on at length.

Yet, for the candidates and their supporters receiving Rome's seal of approval, local competition dissipated. A saint performs miracles as a matter of fact and, therefore, candidates that became saints attracted donations, and often pilgrims, for the local church that housed the body of a saint or some of his relics. Furthermore, Rome's approval could mean the creation of a new religious order, with offices and often a complex bureaucracy, at the disposal of the candidate's supporters. For local activists, the path to canonization was also the path to progressively reducing local competition. This convergence of interests between the goal of the *Congregatio* to create a more modern version of sainthood and the goal of local activists to reduce competition transformed *postmortem* miracles into social facts within the communities that harbored them.

Conclusion

In the previous section, I used the historical case of how the Catholic Church was able to transform sainthood to illustrate a key characteristic of miracles in the modern world, that of being social facts. If the case of the Catholic Church is thus useful for explaining the resilience of miracles to the challenges posed by scientific progress and medicine, it is also interesting in its own right as an example of how an institutional field can be renewed from the center and without conflict (Schneiberg and Lounsbury, 2008). Following Pierre Bourdieu, I see a field as a constellation of objective relationships that structure the interactions between given historical actors (2012). The rules of modern sainthood that I documented above, brought to existence a new actor vis-à-vis the Church and the local authorities – the acolytes, i.e., organized group of believers mobilizing local communities in support of their (defunct) leader.

Fervent believers have always existed in the Christian religion, at least since the arrival of Saint Paul to the shore of Rome, but the organization of their fervor into something more similar to a social movement began with the new rules that the *Congregatio* developed in the aftermath of the Protestant schism. Acolytes, i.e., acquired a new structural role – and with that a system of relationships – that made them an essential part of the field of modern sainthood. A field perspective therefore can help explaining not just the endless proliferation of religious orders within Catholicism but also a key reason for why no other major schisms has occurred within the Church since the sixteenth century: the Church created a position for activists within its religious field capable of incorporating the interests of local actors. The legitimacy of modern sainthood has its roots in the matching between subjective beliefs and objective structure (Bourdieu, 1971).

The new rules that the Church developed allowed for the expressions of different interests and generated a mutually beneficial exchange between central officials, local authorities, and the acolytes. While this exchange emerged through lots of happenstance and conflict (Parigi, 2012), it is interesting to note that it represents a case of institutional renovation from the core of a field. My analysis of modern sainthood highlights a unique path toward institutional change that occurred not only endogenously (Rao et al., 2003) but also from the impulse of the central actor operating in the field, i.e., the Church. Change occurred because the procedures that the Church created were able to integrate the interests of all different actors operating in the field.

Abstract

Mirror neurons, first identified in the monkey brain, respond both when an animal makes a hand movement and when it observes another individual making the same movement. A corresponding but more elaborate system in the human brain has emerged to incorporate such social functions as language, empathy, theory of mind, and cultural learning. The roles of mirror neurons suggest that the mind functions as an embodied system, grounded in real-world simulations, rather than a system based on the manipulation of abstract symbols.

Introduction

> I predict that mirror neurons will do for psychology what DNA did for biology.
>
> V.S. Ramachandran (2000)

This bold prediction has had some impact; typing 'mirror neurons' into Google produces some 2.7 million hits. Among Ramachandran's predictions was that mirror neurons would be seen to underlie the various surges in technology and invention that have created the distinctive human mind – the invention of tools, the 'great leap forward' in cultural and technological innovation of 40 000 years ago, the emergence of language and mathematics, not to mention nuclear power, automobiles, air travel, and even space travel. Mirror neurons were first discovered, though, in the brains of monkeys.

Work undertaken in the 1980s by Giacomo Rizzolatti and colleagues in Parma, Italy, showed that single neurons in the prefrontal cortex of the macaque were specialized for coordinated movements of the hand, such as those involved in grasping an object (e.g., Rizzolatti et al., 1988). They then discovered serendipitously that some of these neurons also responded when the monkeys watched another individual making the same movements (Gallese et al., 1996). These neurons were dubbed 'mirror neurons,' because they seemed to map observed actions on the production of the same actions, as though the monkey perceives an action in terms of how it would itself perform the same action. The activity in mirror neurons does not depend on specific muscular movements; this was elegantly demonstrated by training monkeys to grasp objects using two kinds of pliers, one operating normally, and the other operating in reversed fashion, so that squeezing the arms opened the pliers rather than closing them. The same mirror neurons fired regardless of which pliers were used to grasp an object, even though the hand movements themselves were reversed (Umiltà et al., 2008). Mirror neurons, therefore, seem to be tuned to coordinated, intentional movements, whether perceived or produced, defined in terms of their outcome rather than their muscular components.

These properties seemed to bestow on single neurons almost magical computational powers, but it is now known that mirror neurons are part of an extensive circuit. In the macaque brain, this 'mirror neuron system' (MNS) includes area F5 in the prefrontal cortex, where mirror neurons were first discovered, along with two areas in the parietal lobe, which also contain neurons with mirror properties. The parieto-frontal circuit also receives high-order visual information from the superior temporal sulcus (STS) and inferior temporal lobe, but the neurons in these areas do not have motor properties, and the circuit is under the control of two further areas in the frontal lobes, the presupplementary motor area and the ventral prefrontal cortex (Rizzolatti and Sinigaglia, 2010). It has also been proposed that a similar MNS underlies the perception of emotion (Gallese et al., 2004). The mirroring of perception onto action or emotion is, therefore, a function of complex circuits, and not just of individual neurons.

Although the MNS was originally mapped in the macaque brain, it is now established that homologous systems exists in the human brain. A meta-analysis of 125 studies using functional magnetic resonance imaging (fMRI) revealed 14 clusters of neurons with mirror properties. These were located in areas homologous to those identified in the monkey brain, including the inferior parietal lobule, inferior frontal gyrus, and ventral prefrontal cortex, but also included regions in the primary visual cortex, cerebellum, and the limbic system (Molenberghs et al., 2012). Evidence for individual mirror neurons was also obtained from patients suffering from epilepsy, who had multiple electrodes implanted in the medial frontal and temporal lobes in order to identify potential seizure foci. The patients were asked to execute or observe grasping movements of the hand or facial expressions of emotion, and neurons with mirror properties were identified in the hippocampus and adjoining regions, as well as in the supplementary motor area (Mukamel et al., 2010). It appears that the human brain is indeed well endowed with mirror neurons, perhaps more so than the monkey brain.

The discovery of mirror neurons attracted a flurry of attention in fields as diverse as social psychology, developmental psychology, and linguistics, seeming to explain such phenomena as imitation, empathy, altruism, music, theory of mind (ToM), autism, and the perception of speech, not to mention the contortions my body undergoes when I watch a game of rugby on my TV screen. One problem is that many of these phenomena apply to humans, but not to macaques, where the MNS was first identified. For instance, the very designation 'mirror' implies imitation, but macaques appear incapable of imitation (Visalberghi and Fragaszy, 2001).

 http://dx.doi.org/10.1016/B978-0-08-097086-8.23204-2

Rizzolatti and Craighero (2004) therefore concluded that "the primary function of mirror neurons cannot be action imitation" (p. 172). Later, though, I discuss evidence that the MNS in humans may play a critical role in imitative learning, especially in social contexts.

A more delimited view is that the MNS underlies action understanding. That is, when an observer watches another individual performing an action, the mechanisms for performing that action are activated in the observer at a cortical level, so that the observer then 'understands' that action in terms of how he or she would perform it (e.g., Rizzolatti and Craighero, 2004). This notion too has proven elusive. For instance, mirror neurons appear to be activated in the human brain by meaningless gestures (Iacoboni et al., 1999), raising questions as to whether such actions can be said to be 'understood.' The MNS is also activated when people watch human lip movements or monkey lip-smacks, but not when they watch a dog barking (Buccino et al., 2004), yet there can be little doubt that the barking was recognized and understood. One possibility is that the mirror response is not a necessary component of understanding, but can augment and enrich it. Hickok (2009) gives the example of watching a person playing a saxophone. A nonplaying viewer would certainly understand the action as one of playing the saxophone, but a viewer who was herself an expert might generate internal motor representations enabling her to predict future movements, and determine the level of expertise displayed by the player.

In a further refinement, Rizzolatti and Sinigaglia (2010) argue that the fronto-parietal MNS is specifically dedicated to the understanding of the actions of others 'from the inside,' giving the observer "a first-person grasp of the motor goals and intentions of other individuals" (p. 264). Precisely what this might mean, though, remains to be more fully explored.

The extent to which the properties of mirror neurons revealed from research on monkeys can be applied to functions considered distinctively human is uncertain: Ramachandran's famous remark may be overly optimistic, but need not be totally misguided. The MNS may well have provided platforms for the emergence of human capacities not evident in nonhuman primates. One example is language.

Mirror Neurons and Language

It is widely agreed that language, as a generative, grammatical system, is unique to humans. Some have argued, in fact, that it emerged as a singular event, perhaps due to a fortuitous mutation, in our own species within the past 100 000 years (e.g., Chomsky, 2010) – a theory that smacks of the miraculous. The discovery of mirror neurons in the macaque brain has led to more Darwinian accounts, in which the MNS provided the basis for progressive changes leading to the emergence of speech, and to language as a grammatical system (e.g., Arbib, 2005; Corballis, 2002).

Motor Theory of Speech Perception

As Rizzolatti and Arbib (1998) pointed out, the mapping of perception onto execution was long anticipated by the motor theory of speech perception (Liberman et al., 1967), which holds that speech is understood in terms of its articulation, rather than in terms of acoustic analysis. Mirror neurons in the macaque respond to manual actions, such tearing paper or dropping a stick, whether these actions are seen or heard, suggesting that the MNS does receive auditory input. Critically, though, mirror neurons do not receive input from vocal signals themselves (Kohler et al., 2002). The incorporation of vocal sounds into the MNS probably emerged late in primate evolution, and is perhaps unique to humans (Jürgens, 2002).

As Hickok (2009) has pointed out, though, the motor theory cannot fully explain how we perceive speech. People with production aphasia, or the acquired inability to produce speech, typically retain the ability to understand speech, and some nonhuman species, including chimpanzees (Savage-Rumbaugh et al., 1998), and even dogs (Kaminski et al., 2006; Pilley and Reid, 2011), have been shown to respond to words and simple commands spoken by humans despite being quite unable to produce anything resembling speech sounds. Hickok and Poeppel (2007) suggest a dual-stream model of processing speech. A ventral stream, involving superior and medial temporal lobe, is responsible for the understanding of speech, while a dorsal stream, operating through the posterior and dorsal temporal lobe and the parietal operculum, maps speech sounds on to articulatory representations in the frontal lobe. It is this dorsal stream that is part of the MNS, critical in learning to speak, or in tuning production of speech to what we hear. It may play a role in the perception of speech itself, but is not critical to verbal understanding, which can be accomplished through the ventral stream. A similar division has been proposed for the processing of visual inputs, with a dorsal stream mapping onto action and a ventral stream onto recognition (Milner and Goodale, 2006). The visual streams may play roles in sign language parallel to those of the auditory streams in speech.

The Gestural Origins of Language

Although people (and dogs) can understand language even when unable to produce it, the evolution of language as a two-way communication system probably grew out of the MNS. The MNS in primates has to do primarily with manual grasping, supporting the notion that language itself evolved from manual gesture, not from vocal calls (Hewes, 1973). Area F5 in the primate cortex – the site of the original discovery of mirror neurons – is homologous with Broca's area in the human brain. 'Language,' as Rizzolatti and Arbib (1998) entitle their article, 'is within our grasp.'

Support for the gestural theory comes from the now classic attempts to teach great apes to communicate in language-like ways. Efforts to teach them anything resembling speech failed rather dismally (e.g., Hayes, 1952; Kellogg and Kellogg, 1933), and much greater success was achieved by teaching a form of signed language (Gardner and Gardner, 1969; Patterson, 1978), or by having them point to symbols on a keyboard (Savage-Rumbaugh et al., 1998). Gestural communication has been widely documented among great ages in the wild (e.g., Hobaiter and Byrne, 2011; Pika and Mitani, 2009; Tanner and Byrne, 2010). Manual gestures persist as a critical accompaniment to speech in regular discourse between humans (e.g., Iverson and Goldin-Meadow, 2005), and carry the full burden

of language in the signed languages of the deaf (Emmorey, 2002).

Given the importance of manual gesture as an accompaniment of speech, and the autonomy and linguistic sophistication of signed languages in the deaf, some have queried the notion that manual gesture preceded speech in language evolution, and proposed that they have always been equal partners (e.g., Kendon, 2009, 2012; McNeill, 2005). Some support for this view comes from the strong association between movements of the hands and movements of the face. In the macaque, some mirror neurons respond both when the animal grasps with the hand and when it grasps with the mouth (Gallese et al., 1996; Rizzolatti et al., 1988). In humans, too, there is a strong link between hand and mouth movements; for instance, the way in which a speech sound is uttered is different when the speaker picks up a large object, such as an apple, than when the speaker picks up a smaller one, such as a grape. It is similarly influenced when the speaker simply watches another person picking up these objects (Gentilucci, 2009; Gentilucci and Corballis, 2006). In modern sign languages, movements of the face may play as important a role as movements of the hands (e.g., Emmorey, 2002; Sutton-Spence and Boyes-Braem, 2001).

The evolutionary latecomer, though, may have been voicing. All primates communicate vocally, but their vocalizations are largely instinctive and driven by emotion rather than volition. Primate calls are driven by the limbic system of the brain rather than the motor cortex (Jürgens, 2002). Even chimpanzees, our closest nonhuman relatives, appear to have little intentional control of the voice; Premack (2007), for example, writes that "chimpanzees lack voluntary control of their voice" (p. 13866). Nevertheless recent evidence suggests that chimpanzees, at least, do have limited intentional control of vocalization; for example, they are able to direct food calls at specific individuals, implying both a degree of vocal flexibility and intentional control (Schel et al., 2013). This flexibility, though, pales in comparison to the flexibility and intentional control of the hands in our primate forebears.

A likely scenario is that language evolved within the MNS from the mechanisms of grasping, whether by hand or mouth, in our primate forbears. One limitation of this system in monkeys is that it is transitive, responding only to actions involving the grasping of an actual object, even if that object is hidden behind a screen but the animal knows it is there (Umiltà et al., 2001). In humans, though, evidence from neuroimaging suggests that the MNS responds not only to transitive actions, but also to intransitive ones, where a movement occurs in the absence of an object to be grasped (Rizzolatti and Sinigaglia, 2006), paving the way to imitative or mock actions. Thus pantomime might have been an early precursor to symbolic language. Some degree of pantomime is evident in the natural communications of apes, including orangutans (Russon and Andrews, 2011), although it is unlikely that gestural communication evolved a storylike structure until the emergence of bipedal hominins, and perhaps not even until the emergence of the genus *Homo* some 2.6 million years ago (Thompson, 2010).

A critical development may have been the development of stone tool-making industries, perhaps at the transition from the earlier Oldowan industry to the later, more complex Acheulian industry dating from around 1.7 million years ago. Stout et al. (2008) asked three archeologists experienced in early tool technologies to make Oldowan tools or Acheulian tools, or simply strike cobbles together, and in each case measured their brain activity using a Positron emission tomography scanner with a slow-decaying radiological trace. Only in the case of Acheulian tool making did the brain activity overlap with language circuits, including Broca's area. The active areas also corresponded to the known MNS. Unlike Oldowan tools, Acheulian tool making involves planned sequential action, which may have given rise to pantomime, which might also have been extended to other action episodes, such as accounts of hunting excursions, dating from the middle Pleistocene.

Pantomime, though, is inefficient, and can be streamlined by a process of conventionalization (Burling, 1999), whereby pictorial or iconic representations are gradually replaced by arbitrary signals, shaped to convey information with maximum efficiency and minimum effort. In losing their pictorial quality, though, these arbitrary signals must be sustained and taught by the linguistic community, and transmitted between generations. The process of conventionalization is evident in the development of sign languages. For example, in American Sign language, the sign for *home* was once a combination of the sign for *eat*, which is a bunched hand touching the mouth, and the sign for *sleep*, which is a flat hand on the cheek. Now it consists of two quick touches on the cheek, both with a bunched hand shape; so the original iconic components are effectively lost (Frishberg, 1975). Albeit with a lack of modern cultural sensitivity, Darwin (1872) remarked "on the practice of the deaf and dumb and of savages to contract their signs as much as possible for the sake of rapidity. Hence their natural source or origin often becomes doubtful or is completely lost; as is likewise the case with articulate language" (p. 62).

Because of their spatial nature, sign languages do retain an element of mime, or what has been termed iconicity. It has been estimated, for example, that in Italian Sign Language some 50% of the hand signs and 67% of the bodily locations of signs stem from iconic representations, with a mapping in space and time between the sign and its meaning (Pietrandrea, 2002). In American Sign Language, too, some signs are arbitrary, but many more are iconic. For example, the sign for 'erase' resembles the action of erasing a blackboard, and the sign for 'play piano' mimics the action of actually playing a piano (Emmorey, 2002).

Speech, then, can be regarded as an end-point in the process of conventionalization, whereby arbitrary sounds came to accompany and replace visible movements as the primary carrier of the linguistic message – although, as we have seen, manual gestures remain an important element of normal discourse. This shift may have been the result of a progression of gesture from hand and face to movements internal to the mouth, with the accompaniment of voicing. As Studdert-Kennedy (2005) pointed out, speech itself is a gestural system, involving coordinated movements of the lips, the larynx, the velum, and the blade, body, and root of the tongue. Just when controlled voicing emerged in evolution has been a matter of controversy, with some arguing that articulate speech was possible only in *Homo sapiens* (Lieberman, 2007), with others suggesting that the

Neanderthals, who predated humans by at least 500 000 years, would have possessed the capacity to speak, and perhaps even a fully human language capacity (Johansson, 2013). As we have seen, chimpanzees have some limited intentional control over their calls, but this probably serves to attract attention rather than to convey propositional information (Schel et al., 2013).

On this account, then, gestures of the hands, and perhaps the face, did precede vocalization in the evolution of language, although the switch was more a question of changing dominance rather than an abrupt transition. Even in chimpanzees, vocal calls may accompany manual gestures, primarily to attract or direct attention, while in humans manual gestures serve to embellish speech and occasionally substitute for it. Regardless of the timing of the change, though, language remains a gestural system, evolving through the MNS. The eventual dominance of speech effectively involves the retreat of the gestural repertoire into the mouth, to allow the rest of the body freedom for other activities, such as the use and manufacture of tools, and perhaps for carrying things. In this respect, the emergence of speech may be seen as an early example of miniaturization.

Whether language is voiced or produced manually, then, the MNS seems to have provided the platform for its evolution. The fronto-parietal MNS identified by Rizzolatti and Sinigaglia (2010) shows a remarkable homology with the language network in the human brain. Area F5 in the macaque is homologous to Broca's area in the human brain, and the parietal mirror regions encompass the homologue of Wernicke's area. In the course of evolution, moreover, it seems that the system became increasingly lateralized toward the left cerebral hemisphere. Leftward asymmetries of the homologues of Broca's and Wernicke's areas are evident in the majority of chimpanzees (Hopkins and Cantalupo, 2008), as well as in most humans (Corballis, 2002).

Empathy and ToM

If mirror neurons map perceived movements onto their production, thereby providing for the understanding of the actions of others, one might ask whether they play a social role beyond that of language. One possibility is that mirror neurons form the basis of empathy, the understanding of emotional states in others. A more advanced possibility is that they also allow us to understand cognitive states, such as what others see, think, or believe.

Empathy

One structure that plays a critical role in experiencing the emotions of others, and that has mirror properties, is the insula, a deep cortical structure folded within the lateral sulcus (which separates the parietal and temporal lobes). Its role in one emotion that of disgust, has been well studied. In the monkey brain, the insula receives input from chemoreceptors as well as from bodily states, and stimulation of the insula produces visuomotor and autonomic responses indicative of a feeling of disgust. Stimulating the insula in humans likewise produces a feeling of nausea, and brain imaging has shown that the insula is also activated by the sight of disgusted facial expressions in others (Gallese et al., 2004).

Other evidence suggests that the insula, along with the anterior cingulate cortex, also provides an MNS for pain, allowing people (and perhaps monkeys) to experience their own pain, as well as the pain of others (Singer et al., 2004). The empathy applies to the affective component, but not the sensory one. You may say to an ailing friend 'I feel your pain,' but what you feel is the emotional state, but not the physical pain itself.

The MNS appears also to be involved in understanding other emotions. One of the characteristics of the autism spectral disorder is a lack of feeling of the emotions of others, perhaps as a consequence of a dysfunction of the MNS (Rogers and Pennington, 1991). In one study, children were shown pictures of faces showing emotions of anger, fear, happiness, and sadness, along with a neutral expression, and asked to copy them. Both normal children and high-functioning children with autism were able to imitate the emotions, but in the children with autism, unlike the normal children, fMRI recording showed no activity in the frontal component of the MNS (pars opercularis), or in the insula and amygdala (Dapretto et al., 2006). These results suggest that both normal children and those with autism can detect and imitate emotional expressions, but do so in very different ways. The autistic child may perceive your sadness, but not feel it.

Similar findings have been reported in adults. Both normal adults and those diagnosed with autism spectrum disorder were able to identify emotions expressed in faces. While doing so, the MNS was activated, except that in the group with autism the frontal component was missing (Schulte-Ruether et al., 2011). The authors suggest that it is the frontal component that is responsible for creating the 'emotional bond' between people.

Theory of Mind

The MNS may go beyond empathy to provide information not only on what others feel, but also on what they think or believe. This faculty is known as ToM. Whether nonhuman animals possess this faculty has been a matter of controversy ever since Premack and Woodruff (1978) posed the question "Does the chimpanzee have a theory of mind?" Opinion remains divided. Call and Tomasello (2008) concluded that 30 years of research since the question was posed show that chimpanzees have some understanding of the goals, intentions, perceptions, and knowledge of others, but no understanding of their beliefs or desires. In the same year Penn and Holyoak (2008) remained convinced that "nonhuman animals do not appear to possess anything remotely possessing a ToM" (p. 121).

Even in macaques, though, research suggests a role for the MNS in understanding the intentions of others, which suggests at least limited ToM. Some mirror neurons in the inferior parietal lobule of the macaque are more active when the animal grasps a food item with the intention of eating it than with the intention of placing the food in a container, while others show the reverse pattern. A similar dissociation is recorded when the animal observes the experimenter grasping food, indicating that parietal mirror neurons convey information as to the intention of others (Koski et al., 2002). fMRI studies in humans, too, have shown different activity in the MNS

depending on whether grasping actions are associated with drinking or cleaning up (Iacoboni et al., 2005). Understanding the intentions of others may well have had survival value in our primate heritage, serving as a warning of possible future behavior, as well as creating a capacity for cooperation. In humans, moreover, shared intentionality is a prerequisite for language, the most highly developed of our social tools (Tomasello et al., 2005).

Imitation and Cultural Learning

We humans are distinguished not only by language, but also by the complexities of culture, defined as "the system of shared beliefs, values, customs, behaviors, and artifacts that the members of society use to cope with their world and with one another, and that are transmitted from generation to generation through learning" (Bates and Plog, 1990: p.7). It is also widely agreed that cultural learning depends on sophisticated imitation, and is especially well developed in humans. It has been proposed that this learning depends at least in part on imitation, and is acquired through the MNS. Losin et al. (2009: p. 182) suggest that "the MNS may not only play a role in the acquisition of culturally mediated behaviors, but the MNS itself may be shaped by the presence of culturally mediated behaviors in one's motor repertoire." Like language itself, then, imitation may depend on the adaptation of the MNS to perform a function not well developed in nonhuman species, but essential to cultural learning in humans.

Contrary to the claim of Rizzolatti and Craighero (2004) that the primary role of the MNS in primates is not action imitation, it does seem clear that in humans, at least, the MNS is adapted, through learning, to create what has been termed "automatic imitation" (Heyes, 2011). Brain-imaging studies provide evidence that experience does indeed alter MNS activity. For example, Vogt and Thomaschke (2007) found increased activity in a number of brain regions, including the putative MNS, while participants observed practiced compared with nonpracticed guitar chords. Over a longer period, Cross et al. (2006) showed practice-related increases in MNS activity over five fMRI scans at weekly intervals while their participants learned a novel dance sequence. More pertinent to the question of cultural learning, Calvo-Merino et al. (2005) showed that changes in MNS activity resulting from practice extended to real-world expertise acquired over many years. They found greater MNS activity in experienced dancers when they observed their own style of dance rather than a comparable but unfamiliar style. Potentially, at least, daily experiences, including those specific to the culture we live in, can influence MNS function, and through overlearning explain our automatic tendency to imitate. And of course language itself depends heavily on imitation, and is culturally constrained – there are some 7000 different languages in the world, each more or less impenetrable to others.

Although automatic imitation is influenced by experience and culture, there may be a hard-wired component as well. Just hours after birth, infants imitate facial gestures such as protruding the tongue, a finding that has been much replicated (Meltzoff and Decety, 2003). One model as to how the MNS might change as a result of experience has been proposed by Iacoboni (2005). He suggested that the STS, which is part of the MNS but does not include the motor component, constructs a higher-order description of the observed action. This description is transmitted to parietal and frontal components of the MNS, where the goal of the action and motor components to achieve the action are encoded. The motor plan is then fed back into the STS, where its sensory consequences are compared with the visual description of the original action. This circuit leads to progressive refinement of the MNS circuitry.

Automatic imitation pervades our social interactions. People tend to yawn or laugh when someone else yawns or laughs, or even the tendency of people in conversation to imitate each other when in conversation, perhaps crossing their legs or holding their arms in similar fashion (Hurford, 2004). These imitative tendencies may help to strengthen social bonds. Nevertheless they can interfere with intentional behavior. In spoken discourse, for example, a natural tendency to imitate what one hears must be suppressed to sustain effective communication. A compulsive tendency to repeat heard utterances, known as echolalia, is sometimes observed, and attributed to frontal lobe deficits (e.g., Grossi et al., 2013; Cho et al., 2009). A number of studies have shown that when people are instructed to make simple finger movements in response to neutral cues, their movements are inhibited when videos of incompatible movements are presented simultaneously with the cues (e.g., Cross et al., 2013; Stürmer et al., 2000). Automatic imitation is reduced when the frontal node of the MNS is stimulated through transcranial magnetic stimulation (Catmur et al., 2009). Adaptive social behavior depends on the interaction between control processes, mediated by a 'prefrontal control system,' and the more automatic reactions of the MNS (Cross et al., 2013).

Conclusions

As Ramachandran anticipated, mirror neurons have indeed provided insight into many aspects of cognition, some of them distinctively human. These include language, empathy, ToM, imitation, and cultural learning. Although mirror neurons were first identified in monkeys, their extensive and distinctive roles in human condition illustrates the fact that the MNS is an adaptive system, providing complex but automatic calibration to social contingencies. The system is part of our biological heritage, shaping us, and indeed our evolutionary predecessors to life among members of the same species.

The MNS has also been taken to support the notion that cognition is embodied (Barsalou, 2008), such that perceiving the world is computationally entwined with our bodily movements, and thought itself is made up of internal simulations of real-world events and actions. This stands in contrast to the idea that thought is essentially computational and symbolic, as in a digital computer. Again, it is opposed to the Chomsky's (2010) view of language and thought (or what he calls 'I-language'), which is that symbolic representations and computational algorithms emerged in humans without reference to the external world – a view incompatible with Darwin's theory of evolution by natural selection. The roles

of mirror neurons may remain incompletely specified and indeed 'fuzzy' (Hurford, 2004), but they do provide the basis for a more Darwinian perspective on the evolution of thought, and for a paradigm shift from computer-based models of the mind toward models that are based on real-world interactions with the biological and social environments.

Misdemeanor Offenses

DeAnn Kalich, Margot Hasha, and Craig J Forsyth, University of Louisiana, Lafayette, Lafayette, LA, USA

Abstract

Misdemeanor offenses are largely ignored in the literature, because attention is usually focused on the most serious and violent crimes. Most people entering the American criminal justice system do so for misdemeanor offenses. These offenses, while considered petty, are prohibited by misdemeanor laws. *Mala prohibita* crimes (wrong only because they are prohibited by law) refer to behaviors that violate contemporary standards only, such as white-collar crime and illegal drug use. These crimes represent society's attempts to regulate behavior that offend the moral sensibilities of particular people during specific periods of time in certain locations, and correspond generally to misdemeanors. This article examines the role of moral entrepreneurs in constructing definitions of crime/deviance as misdemeanors/felonies and subsequent examples of misdemeanors in American society. An examination of the very real consequences to being labeled guilty of a misdemeanor offense is also presented.

Misdemeanor offenses are largely ignored in the literature, because attention is usually focused on felonies: the most serious and violent crimes, such as robbery, rape, and murder. In the United States, approximately 1 million felony convictions are entered annually, while more than 10 million misdemeanor cases are filed during the same period. In fact, in most states, misdemeanor dockets are four to five times the size of felony dockets, with these wrongful convictions never making it into headlines specifically because they are petty offenses, for example, trespassing, disorderly conduct, and loitering. Most people entering the American criminal justice system do so for misdemeanor offenses. These offenses, while considered petty, are prohibited by misdemeanor laws. How we process misdemeanors in the United States represents an immense public institution – one so large and powerful that it deserves far more scrutiny than has been afforded it thus far.

When exploring criminal offenses, it is helpful to distinguish between *mala prohibita* crimes and *mala in se* crimes, with the latter considered more serious than the former. *Mala in se* (evil in themselves) crimes refer to behaviors that violate moral codes as well as traditional norms. This category encompasses the core of the criminal code, including property crimes, violent crimes, robbery, and homicide, and corresponds to felony crimes. Conversely, *mala prohibita* crimes (wrong only because they are prohibited by law) refer to behaviors that violate contemporary standards only, such as white-collar crime and illegal drug use. These crimes represent society's attempts to regulate behavior such as drug use, gambling, and prostitution that offend the moral sensibilities of particular people during specific periods of time in certain locations, and correspond generally to misdemeanor crimes. *Mala prohibita* crimes are likely to vary over time and across jurisdictions. An example is the consumption of alcohol in the United States, which shifted from legal to illegal during Prohibition with the ratification of the 18th Amendment and the Volstead Act, and back to legal again through the ratification of the 21st Amendment, which repealed the 18th. Similarly, casino gambling is legal in some states and illegal in others, with many states also having sanctioned lotteries (Vito et al., 2007).

Moral Entrepreneurs

It is sometimes difficult to define misdemeanor crime, because the term refers to a diverse collection of offenses that are grouped differently across jurisdictions. Some social science researchers reference misdemeanors as 'morality offenses.' This perspective states criminal law is used to impose minimum standards of morality on a citizenry. The 'minimum standards' are considered 'misdemeanors.' The laws defining offenses which are against public morality are used to set the standards for acceptable behavior. Howard Becker argues that groups of like-minded individuals act as *moral entrepreneurs* to define the behavioral standards that will be acceptable to a specific community. Also referred to as 'rule creators' and 'rule enforcers,' moral entrepreneurs are in the business of constructing definitions of crime/deviance and then for policing the subsequently identified rule violations. Their chief concern is the persuasion of others, not the means by which that persuasion is achieved.

While misdemeanor offenses are generally considered to be less serious than felony offenses – as evidenced by the degree of legal censure present in the scheduled punishment for the misdemeanor – these offenses often are treated as quite serious by groups of moral entrepreneurs who themselves may hold little or no official legal status in their community. The sense of morality that is offended in the act of the misdemeanor is the sense of morality belonging to the moral entrepreneurs. For these groups, then, it is vitally important that the punishment assigned to the rule violation does, in fact, occur. Often, offenses that are classified as misdemeanors are in fact of great importance to the dominant culture groups, who are responsible for having defined the laws which target the behaviors in question. The label of misdemeanor may therefore carry a small official sanction relative to that carried by a felony offense, but the unofficial response of some interested observers to the rule violation is one of moral outrage and therefore of great importance. This is because the rule that has been defined as a morality offense is a rule that reflects the values and morals of the population of interested observers (what Becker refers to as moral entrepreneurs), typically those inhabiting upper social strata in the dominant culture.

When the efforts of rule creating moral entrepreneurs are successful and new sets of laws and enforcement agencies finally institutionalize their crusades, 'rule enforcers,' who are comprised of police and court systems, attempt to not only enforce these laws but also to justify their own roles with respect to their interactions with the public. These rule enforcers represent another category of moral entrepreneur, according to Becker. He asserts that rule enforcers are in a bind: to be too effective might indicate that society does not need them, while not being effective enough might lead to the societal belief that they are failing at their roles. As rule enforcers, these groups are less concerned with the content of the rule than they are with performing their jobs. And, because rules (and thus, laws) change over time, and what was once unacceptable might now be accepted in society (such as the legalization of marijuana use in some states), rule enforcers often devote much time and energy to coercing respect from those with whom they interact. As such, persons may be deemed deviant not so much for breaking the rules as for demonstrating disrespect to the rule enforcers. According to Becker, these police and judicial officials view human nature pessimistically as a result of their constant exposure to 'willful deviance.'

Labeling an individual who commits a misdemeanor as 'deviant' depends upon factors outside the actual behavior, such as if an official experiences pressure to justify his/her position at a given time; whether or not the rule enforcer feels respected by the actor; whether the crime committed was performed by an amateur (who is more likely to be caught, convicted, and labeled deviant); or whether the misdemeanor committed is even high on the priority list of the rule enforcer.

Social theorists such as Joseph Gusfield have posited that official social recognition of some rules as valid and moral rules is a way of conferring higher social status to the groups whose values are reflected by those rules. Thus, elevating a group's norms behavior to the status of a law is a way of reinforcing the superiority of that group's ideas and morality relative to the ideas and morality of other, competing groups. This is true despite the seriousness of the sanction or legal response assigned to the rule violation. The fact that the behavior is defined as a violation at all is enough to accomplish what is needed in defining one social group as superior to another. Social groups that are successful in having their definitions of good and bad, right and wrong, moral and immoral encoded into law are therefore reaffirmed as superior to those groups whose ways of life are not recognized as legal. Misdemeanor crimes often are behaviors that are criminalized because particular groups prohibit the behaviors on moral grounds. Moral entrepreneurs will wage moral crusades in order to manufacture widespread public concern about an issue and to increase support for criminalizing that behavior in the written law. They tend to be righteous, sometimes self-righteous and fervent in their efforts, and their mission is to promote their sense of morality. Many legal campaigns have the character of a moral crusade to criminalize behavior that may not in fact be as dangerous or expensive to society as other noncriminal behaviors.

One example of moral entrepreneurs who have engaged in moral crusades is the Women's Christian Temperance Union and the U.S. Prohibition Movement. This alliance brought together conservative Christian activists, Women's Rights groups, and anti-Child Labor groups for a common cause. According to Gusfield, Temperance (moral) abstainers sought to correct the behavior of (immoral) drinkers. Drinking and nondrinking historically have been methods by which to identify members of a subculture, thus drinking and abstinence eventually became symbols of social status. Through the Temperance Movement, a declining social elite comprised of White Anglo-Saxon Protestants attempted to retain social power and leadership authority. By the 1830s, abstinence had become an aspect of middle-class membership, a necessity for social upward mobility, and a component of public morality. The passage of the 18th Amendment in 1920 was the apex of the victory of Protestant over Catholic and tradition over modernity.

Another group of moral entrepreneurs might be the U.S. Federal Narcotics Bureau, especially while under the direction of Harry Anslinger. Craig Reinarman argues that most of the antidrug campaigns across history in the United States are moral crusades, such as the antimarijuana and anti-opium movements founded during the early twentieth century. Similarly, groups such as Mothers Against Drunk Drivers (MADD) and Students Against Drunk Drivers have organized to persuade public morality to convert and criminalize the act of drinking and drinking. More recently, an alliance has formed among conservative Christian activists and Feminists opposed to human trafficking. The role of moral entrepreneur is a role that could be applied to any social group that seeks to convert others to the primary group's way of thinking about a particular issue affecting society. Thus, it can even be argued that the activist parent group (modeled after MADD) known as Bothered About Dungeons and Dragons (BADD) is also a group of moral entrepreneurs that has attempted to have the fantasy game 'Dungeons and Dragons' banned from sale, or prohibited for underage players. Parents in the group have concerns about the connections between the game, satanic worship, and the occult and suicidal behavior in teenagers. Though BADD has not been successful in redefining that specific practice of game playing as a misdemeanor crime, the crusade continues.

It can likewise be argued that groups such as the Ku Klux Klan (KKK) act as moral entrepreneurs when attempting to police the behaviors of others according to the values espoused by the Klan. Historically, behaviors deemed immoral by the Klan have in fact been criminalized as misdemeanors (miscegenation, prostitution, gambling, and alcohol consumption). While the KKK has been prominently featured in historical accounts of racist and nationalistic violence, less attention has been given to its active role as rule enforcers for conservative morality as an extension of the group's support of Protestant fundamentalism. After World War I, membership in the Klan swelled in response to social anxiety about ongoing chaos in social relationships with African-Americans, Catholics, Jews, labor radicals and liberals. In addition, a new 'enemy' was identified in the guise of white men and women who deviated from the Klan's moral code. Nancy Maclean argues that the Klan could be petitioned on behalf of wronged victims of immorality to reinforce the boundaries between right and wrong by enforcing sanctions against the immoral offenders. Thus,

Maclean cites a woman whose husband was both an alcoholic and a gambler, who refused to grant her a divorce with alimony and instead slandered her with an accusation of adultery. The woman was therefore unable to financially care for their two children, and in response, petitioned the KKK for help in obtaining the justice denied to her by the courts. This was a routine role for the Klan of the 1920s, and historical documents show that a preponderance of Klan violence at that time period in history focused on offenders who were atypical in race (white) and gender (women). For example, white women in Macon County, Georgia, were frequent targets of the Klan for alleged consumption of alcohol and sexual promiscuity.

Finally, social science research demonstrates that moral enterprises (where specific behaviors, beliefs, and conditions are linked to moral meanings) are often sufficient to confer status to a group relative to other groups without the need for rule enforcement or punishment for rule violations. Thus, misdemeanor crimes by their very existence and encoded presence in law are sometimes sufficient to the needs of the moral entrepreneurs. No official sanctions are necessary. Specifically, Joseph Gusfield argues that laws can exist to perform either instrumental or symbolic functions. Instrumental functions of law serve to modify behavior. Thus, a law is enacted and when enforced, behaviors change. An example can be found in the seatbelt laws that were legislated in Texas during the mid-1980s. When the initial seatbelt law was approved, few Texans modified their practices with regard to buckling their seatbelts. In order for more modifications of behavior to occur, citizens required enforcement of the new law. When the Texas Department of Public Safety allocated monies for the enforcement of the new law, and subsequent and steep financial penalties were levied against violators, most drivers began to buckle their seatbelts. The enforcement of the law provided an instrumental effect. Without enforcement, no instrumental change to behaviors would have occurred. Gusfield states that laws often are passed without provision for enforcement. These laws he calls symbolic laws – symbolic because they were passed at all. No enforcement is intended, but the meaning behind the codification of the rule violation is a status conferring one. A group has its norms elevated to the status of law and is thus of higher status than those of other groups. Gusfield says that enforcement of the symbolic law would destroy the function of this type of law. Thus, during the U.S. Prohibition Movement, laws against drinking were predominantly symbolic laws with little or no monies provided to fund their enforcement. Gusfield argues that this is because the group that advocated for prohibition was the group that held status and power, and the Temperance Movement was designed to target a behavior found among newer immigrants to the United States, whose increasing population size was beginning to threaten the power found in maintaining the status quo. Yet, if laws against drinking were enforced, assimilation of groups would have resulted and meant the disappearance of the ruling class. Symbolic laws (laws without enforcement) were therefore enacted instead. Many social theorists have suggested that the purpose of a misdemeanor crime category is to harbor the products of the activities of moral entrepreneurs who have engaged in moral crusades.

Levels of Crime: Felonies, Misdemeanors, and Infractions

Crimes are classified according to their severity, with the particular classification influencing both the substance and the procedure of a criminal charge. The mildest crimes are known as infractions, and the most serious are felonies. Misdemeanor violations of the law fall between felonies and infractions, in terms of both severity and punishment. Infractions, also referred to as petty offenses, are not considered crimes in some states. However, even in jurisdictions that treat infractions as criminal offenses, incarceration is not usually the punishment. When it is, confinement occurs in a local jail. Most persons convicted of a felony and sentenced to incarceration are sent to state prisons, or, in the case of a felony, to federal prison. Misdemeanor offenses, less serious than felonies but more serious than infractions, are generally punished by a fine and/or incarceration in a local jail, which generally also house people awaiting trial. With very few exceptions according to state, people convicted of misdemeanors do not lose any civil rights, as opposed to convicted felons. However, there are circumstances in which misdemeanor conviction can interfere with job prospects and certain civil privileges; for example, a school bus driver receiving a first DUI who may lose her driver's license.

Felonies

Felonies are the most serious class of criminal offenses throughout the United States. Many jurisdictions separate felonies into their own distinct classes, with repeat offenders convicted of committing heinous felonies receive more severe punishments than first-time offenders convicted of committing less cruel or injurious felonies. Depending upon the circumstances, felonies are punishable by a fine, imprisonment in excess of 1 year, or both. Historically, in common law, felonies were offenses that violated the moral standards of a community. Today, many crimes classified as felonies still offend the moral standards of American communities and include such offenses as treason, terrorism, murder, rape, kidnapping, robbery, arson, and burglary, among others.

Infractions

An infraction is a violation of an ordinance, a municipal code administrative regulation, and state or local traffic rules. In states that do not criminalize infractions, such crimes are treated as civil offenses. Similar to misdemeanors, infractions are often defined in broad language. Although incarceration is rare, when it does occur confinement is limited to serving time in a local jail.

Misdemeanors

A misdemeanor is a criminal offense for which a fine and/or a sentence to a term of imprisonment not in excess of a year may be imposed, with confinement occurring in a city our county jail rather than a state or federal prison. Misdemeanors

are classified differently in various states and classifications are based upon level of severity of the crime. All states as well as the federal government classify misdemeanors into Classes A, B, and C, high or gross, ordinary, and petty. High or gross misdemeanors are defined in some states as any crime that is not a felony or an ordinary or petty misdemeanor.

Class A misdemeanors are the most serious and carry fines of up to $4000, along with jail terms of up to 1 year in the county jail. The U.S. Code establishes a sentence of 6 months to 1 year in jail, although some state laws vary in fines and jail terms. Examples of Class A misdemeanors include second DUI charges, assault charges, vehicular theft, and possession of an illegal weapon. These misdemeanors are not easily expunged.

Under the U.S. Code, Class B misdemeanors carry 30-day to 6-month jail terms and fines of up to $2000. State codes vary in sentencing, with one state assigning jail sentences of 6 months or less and fines of $500. In this same state, prostitution is considered a Class B misdemeanor. Other examples of Class B misdemeanors include first-time DUI offenses, criminal trespassing, petty thievery in the amount of $50–500, and law violators who evade arrest.

Class C misdemeanors carry jail terms of 5–30 days under the U.S. Code and not more than 30 days in jail with fines of $50 or less under most state laws.

Misdemeanor convictions usually do not result in the loss of civil rights, but they may result in the loss of privileges, such as professional licenses, public office, or public employment, known as *collateral consequences of criminal charges*. Such sanctions are more common when the misdemeanor is related to the privilege in question, such as the loss of a driver's license by a taxi driver convicted of reckless driving. Another example of collateral consequences related to misdemeanor conviction involves moral turpitude – generally evaluated on a case-by-case basis. A prominent example is found in the U.S. Constitution, which provides that the President of the United States may be impeached and subsequently removed from office is found guilty by Congress for 'high crimes and misdemeanors,' the definition of high crimes being left to Congressional discretion.

Unclassified Misdemeanors

In the United States, when a statute does not specify a class for misdemeanors, they are referred to as *unclassified*. Such laws are enacted by legislators when they wish to impose penalties falling outside the framework specified by each class. First-time marijuana possession is an unclassified misdemeanor in some states and is punishable by up to 30 days in jail rather than the usual fines and jail sentences of the classified misdemeanors. Some states categorize misdemeanors as Class A, Class B, and unclassified.

Eleven Types of Misdemeanors

1. *Simple Assault* – Assault is an intention threat to do violence to another person. While often confused with *battery*, which is the actual touching or striking of another person, assault involves verbal threats or actions. Assault and battery involves the threat of another's safety combined with actual unwanted physical contact. Simple assault is a common misdemeanor. It is defined as assault without the intent of injury. However, exceptions are simple assault on police officers, elected officials, and social workers, which constitute felonies. Simply invading another's personal space is a simple assault.
2. *Petty Theft* – Petty theft is an umbrella term encompassing larceny, stealing, embezzlement, and any other instance of taking someone's property against that person's will. In most jurisdictions, petty theft is identified by a value amount of $500 or less. While stealing property from someone's home is petty theft, shoplifting or stealing from one's employer is also petty theft. The charge of petty theft may be elevated to a felony if the offender has a criminal history involving prior thefts. *Larceny* refers to the wrongful taking property and occurs when, with the intent to deprive the owner, an individual appropriates, obtains, or withholds the property from the owner. Punishment for the crime of larceny varies in severity based upon the value of the wrongfully taken property. Grand larceny involves property of larger scale, as opposed to petit larceny of small-scale property.
3. *Solicitation* – Solicitation occurs when one person attempts to persuade another to commit a crime. The most common form of solicitation is prostitution, the encouragement by one person of another to pay for sex. It is also a misdemeanor to procure customers for a prostitute, known as *pandering*. Another form of solicitation is *panhandling*, a request made in person for an immediate donation of money or other reward. Panhandling can occur through passive manipulation of emotions (especially guilt) or aggressive intimidation tactics. During the Great Depression of the 1930s, and in other cultures around the world, such actions as panhandling (or begging, as it is more commonly known) are considered socially appropriate and even honorable for the context. For example, religious requests for financial support of the ministerial class who do not work for pay are accepted by most social observers across cultures. Some U.S. jurisdictions now criminalize panhandling as misdemeanors, though social theorists and political commentators argue against the practice as one which unevenly discriminates against the homeless.
4. *Trespassing* – Trespassing occurs when a person unlawfully intrudes on another's property. Trespassing laws vary among jurisdiction but are commonly categorized as misdemeanors. It is common to see 'no trespassing' signs in places such as schools and private hunting grounds. Whether the property is public or private, going onto another person's property without their knowledge or consent is trespassing, whether or not damage is done. Entering another person's home does not fall into the purview of trespassing; rather, such a violation is *breaking and entering*. Exceptions to trespassing laws include police, meter readers, and government surveyors.
5. *Arson* – Arson is the intentional damage of property by fire. Setting fire to any building or structure, whether public or private, is a misdemeanor. Burning down a home or business for the purpose of making an insurance claim is arson as well as insurance fraud. Misdemeanor arson

requires that the act is malicious or reckless, regardless of motive. If a house is vacated, unfit for human habitation, or closed up, its burning is not arson. If a dwelling is burned under the impression that it is abandoned, but someone actually lives in it, then arson has been committed. Accidental fires are not considered arson.

6. *Contempt of Court* – Contempt of court involves the act of defying authorities during court proceedings. A contempt of court charge may be imposed upon anyone in the courtroom, including attorneys, witnesses, jurors, court officers, or anyone who interrupts the proceedings. *Civil contempt of court* occurs when someone refuses to abide by a judge's decision in a case. An example is a child support case in which one parent refuses to pay the amount mandated by the court. An example of *criminal contempt of court* occurs when an individual physically interrupts a court hearing by shouting at court officials or witnesses.
7. *Stalking* – Stalking as a misdemeanor crime involves following or harassing a person continuously and causing that individual emotional distress. Any unwanted intrusion or communication by a person to another person falls within the definition of misdemeanor stalking and is a form of mental assault in which the intruder breaks in the lifeworld of the victim. Stalking behaviors include physically following someone, making harassing phone calls or text messages, or electronically targeting victims over the Internet and through monitoring software, hidden cameras, microphones, and GPS tracking units, all of which can pose a real threat to another's safety and perception of well-being. Stalking or harassing another is typically sanctioned as a misdemeanor crime for first offenses, but subsequent stalking convictions are usually punished as felonies.
8. *Possession of Illegal Substances* – Drug possession involves having illegal drugs in one's pockets, purse or wallet, or vehicle. Small amounts of illegal drugs for personal use usually result in misdemeanor charges, while larger amounts for the purposes of distribution constitute felony drug possession.
9. *Driving Under the Influence* – Driving under the influence involves operating a vehicle while intoxicated from alcohol or while under the influence of any illegal substance. Convictions for DUIs can result in the loss of one's driver's license, mandated community service, jail time, and fines. Those found guilty of DUIs with a history of other similar offenses often experience harsher penalties than do first-time offenders.
10. *Criminal Mischief* – This misdemeanor charge is applied to individuals who knowingly and intentionally injure, damage, move, deface, tamper with security devices or destroy any property of another or public property without consent. Security devices include fire extinguishers, fire hoses, fire escapes, emergency exits, emergency escape equipment, life preservers, life rafts, alarms, or devices intended to warn of danger or emergency, such as guard rails, traffic signals and signs, or railroad grade crossing signs. Criminal mischief also occurs when without consent an individual tampers with the property of another or public property for the purpose of endangering or interfering with another person or that person's property or use of the property. Criminal mischief includes destruction of property such as breaking windows or altering property through graffiti. It also includes the intent to impair the functioning of any computer, computer system, computer network, computer software, or computer program, through such actions as computer hacking, alteration of a computer, computer system, or computer data or software contained in the computer. To be considered a misdemeanor, damage to the property must not exceed $1000. Property damage in excess of $1000 is categorized as a felony.
11. *Indecent Exposure* – Because the term 'indecent' is difficult to define, indecent exposure is the misdemeanor with the most variability across jurisdictions. For example, in Washington State, indecent exposure has been defined as intentionally exposing one's genitals with the knowledge that the action can cause reasonable alarm. Often indecent exposure is committed for the sexual gratification of the offender or committed to entice a sexual response from another. Exposing one's genitals does not include baring the female breast (which, if considered indecent exposure, would interfere with breast-feeding mothers). However, exposing oneself to a minor under the age of 14 years qualifies as gross misconduct, a felony. Additionally, indecent exposure reaches the level of sexual assault if any physical contact is made. In most cases, the first conviction for indecent exposure subjects one to misdemeanor penalties like a fine or a few months in the county jail. Second offenses would likely rise to felony status, leading to a state prison sentence. In some states, any indecent exposure conviction subjects the offender to a lifetime mandate of registration as a sex offender.

Not Petty Consequences

Because misdemeanors are considered petty offenses, data about them are sparse. Some states, like California, do not count misdemeanor convictions at all. Because the massive misdemeanor legal apparatus is very informal and overcrowded, petty offenders routinely are denied counsel, even when they are constitutionally entitled to an attorney. When they do have access to an attorney, the process is referred to as 'meet them and plead them lawyering.' This reflects the reality that once people charged with misdemeanors get to court, they often are pressured by players in the system to plead guilty, without full knowledge of their civil rights or the nature of the charges against them. If the accused pleads 'not guilty,' bail is set, with approximately 75% of defendants unable to pay. Consequently, innocent defendants commonly plead guilty just to get out of jail. Millions of Americans are thus punished without due process and soon learn that, at least when it comes to minor offenses, the law and evidence are not part of the process.

According to one argument, minor misdemeanor crimes may not actually matter too much. Since guilty pleas by defendants typically result in a fine or probation (not jail time), perhaps these minor crimes should be handled in the quickest,

cheapest way without counsel or due process, especially given the deplorable lack of resources system wide. Indeed, petty offenders may actually get out of jail sooner (if sentenced to jail time) if they plead guilty. Moreover, it is widely assumed that millions of these defendants actually are guilty, so rushing them through the system will not result in much of a miscarriage of justice.

However, it must be pointed out that these petty convictions are not minor. These offenses are punished with fines that some individual defendants simply cannot pay. Additionally, convictions of any type can hurt job prospects; affect eligibility to obtain professional licenses; negatively impact child custody; threaten public housing; jeopardize food stamps, student loans, and health care; or lead to deportation.

Mismatch on the Labor Market

Abstract

Separate sections of the literature deal with search behavior – or the process through which job matches occur – and skill mismatch, which is concerned with outcomes and includes qualifications mismatch, skills mismatch, and skills obsolescence. Causes of mismatch may reflect the qualities of job seekers, their preferences, or their membership of particular groups. Consequences may manifest themselves in terms of wage or productivity adjustments. Recent work using panel data has allowed some of these effects to be identified more clearly. The main policy implication is that attention should focus on skills mismatch rather than on qualifications mismatch.

Introduction

The term mismatch covers disparate areas of the literature. One part of this is largely concerned with job search and focuses on the process of job filling or job change. Another strand focuses on skill mismatch and is largely concerned with the outcomes resulting from this process. When the labor market is subject to severe adjustments, such as those resulting from skill-biased technological change or the hollowing-out phenomenon in which medium-skilled jobs are automated and labor is displaced, some mismatch is inevitable – some workers find themselves with the wrong skills and employers search for those with the, desired, new skills. An alternative approach, adopted by Sattinger (2012), is to distinguish between short-run mismatches occurring between workers and jobs, and long-run aggregate mismatches which arise from shifts in supplies of and demands for workers. In what follows, we first give a brief account of the job-search process and then consider the skill-mismatch literature in some detail.

Job Search

Short-run mismatches can occur as a result of heterogeneity in terms of both jobs and workers, combined with imperfect information and labor-market frictions. Search will then be costly for both employers and those seeking employment. As Pissarides (1990) and Petrognolo and Pissarides (2001) put it, when searching for a job a worker does not know which firms will be willing to make a job offer. Then, the job seeker has to decide whether to accept an offer, depending on their reservation wage, or to continue searching. An employer may fill a job vacancy before the best available candidate is found, because it is expensive to have an unfilled vacancy. Similarly, an employee may accept a job before the best vacant job is found. Under such circumstances, perfect matching will be rare. This exchange process can be summarized by a well-behaved function that expresses the number of jobs formed in any period in terms of the number of workers looking for jobs, the number of employers looking for employees, and a small number of other variables. These variables will be related to the stage of the business cycle in which we are. The simplest form of the matching function is

$$M = m(U, V) \qquad [1]$$

where $M =$ the number of jobs formed during a given time period, $U =$ the number of unemployed workers looking for work, and $V =$ the number of vacant jobs.

A steady state relationship between the unemployment rate and the vacancy rate can be derived from [1]. Let U and V be the number of unemployed workers and job vacancies respectively, and N and L be the level of employment and the labor force respectively, so that $L = (N + U)$. Define the unemployment rate $u = U/L$ and let the vacancy rate be $v = V/N$. Assume that the job-separation rate is z, so that total separations are $S = zN$. Then, imposing constant returns to scale on m (.) and noting that in the steady state the number of matches M equals the number of job separations S, we can obtain the Beveridge curve as in **Figure 1**.

Equilibrium occurs when the number of vacancies equals the number of unemployed workers – on the 45° line from

Figure 1 The Beveridge curve.

the origin. If, however, the economy runs into a recession the number of unemployed workers will exceed the number of job vacancies to the right of the 45° line or, in other words, labor supply will exceed labor demand. If the economy overheats, the number of vacancies will exceed the number of unemployed workers to the left of the 45° line, that is, labor demand exceeds labor supply. If there is an increase in structural imbalances in the economy, the whole Beveridge curve may shift outwards, say from A to B. Supply and demand will be in balance on B, but frictional and (or) structural unemployment will be higher. With excess demand there will be labor shortages and with excess supply labor surpluses.

What constitutes a labor shortage is not, however, straightforward. An employer who cannot find sufficient workers because the wage has been set too low is not suffering from a genuine shortage. Further, skill gaps in which the existing employees lack the appropriate skills to do the job properly require different measures to overcome the problem, such as additional training. In some instances skill shortages are the manifestation of buoyant demand and are associated with increasing sales in the sector. In other cases they are the manifestation of falling demand where skilled workers are leaving a declining sector, faster than the sector declines as shown in Mavromaras et al. (2013c). How employers respond to skill shortages is also not straightforward. Healy et al. (2011) use a large longitudinal sample of Australian small and medium size enterprises (SME) to show that the most common employer responses to experiencing skill shortages are longer hours by existing staff, subcontracting, internal training, and reductions in production. Paying higher wages to attract the needed skilled workers is only used by 16% of all employers.

Hiring standards may be adjusted because of skill shortages according to the stage of the business cycle and the state of the labor market. When demand is buoyant, employers may be forced to take on workers who are somewhat lacking in the personal traits that employers would normally demand. In contrast, when demand is depressed and labor is in plentiful supply employers may raise their expectations and seek qualities beyond those which are technically required. It is in times of labor-market tightness that employers may be forced to hire workers who are underqualified or underskilled. In contrast, when the labor market is slack overqualified or potentially overskilled workers may be obliged to apply for jobs beneath their capabilities. Cross-sectional analyses may fail to pick up these subtleties of the business cycle. Nevertheless, there is information regarding disequilibrium manifestations of mismatch as proposed by Mavromaras et al. (2013c), who show how combinations of complementary short-length time series data on education and employment outcomes can be used to monitor skills disequilibrium at the level of occupations for the whole labor market.

Skill Mismatch

It is now well established that many workers are employed in jobs for which their current qualifications are not a requirement, while others lack the qualifications that are required of current recruits. In addition, some workers possess skills and abilities which are underutilized in their current job, while others struggle to cope because, through lack of training, they do not possess the necessary skills. We use skill mismatch as a generic term to cover both forms of mismatch (in qualifications and in skills); the term skills mismatch refers to the narrower concept which includes skills and abilities, but excludes qualifications mismatch. The starting point for this branch of the labor economics literature was Richard Freeman's book entitled *The Overeducated American*, which first made use of the term overeducation, meaning that some graduates could not obtain jobs which required a degree or, as Freeman put it,

> The college job market underwent an unprecedented down turn at the outset of the 1970s, with young graduates just beginning their careers most severely affected. Real and relative earnings of graduates dropped, employment prospects and occupational attainment deteriorated, and large numbers were forced into occupations normally viewed as being below the college level. For the first time in recent history the economic value of an investment in college education fell, though with considerable variation among professions and groups.
>
> Freeman, 1976, p. 184

Freeman noted that the above outcome was not anticipated by conventional economists working in the human capital or economics of education field. Despite the fact that many of Freeman's most pessimistic predictions for the future of higher education did not come to pass, his work stimulated a stream of papers that consider mismatch across several dimensions, covering different time periods and countries, and extending to all classes of labor.

By any standards, when we look at the labor market, the extent of mismatch is considerable. Indeed, Slonimczyk (2013) shows that a substantial fraction of the increase in overall inequality in the United States over the period 1973–2002 can be attributed to an increase in mismatch rates and mismatch wage premia. For example, around 20% for males and 48% for females of the increase in the Gini coefficient can be attributed to surplus qualifications. In **Table 1** we summarize the incidence of vertical mismatch (that is, when the level of the worker's qualifications is different from the level usually required for the job) in relation to qualifications, constructed from existing studies.

In addition to vertical qualifications mismatch there may be horizontal mismatch in which the level of qualification is appropriate, but the type is not. Its measurement depends on

Table 1 Qualifications mismatch

The Utilisation of Human Capital from Education in Australian Labour Markets. Over-Education? Ph.D. thesis, University of Melbourne.

the identification of occupations that correspond to each field of study, but in some cases the relationship will be imprecise. Nonetheless, Randstat (2012) found that 23% of workers in EU27 were affected by horizontal mismatch in 2009. Data from the fifth wave of the European Working Conditions Survey (EWCS) 2010 suggest that 31% of employees are overskilled, a similar proportion to those who are overqualified, while13% are underskilled. In all possible types of mismatch, the least satisfactory case seems to be a situation where employees are both overqualified and overskilled (see below). According to EWCS 2010, about 35% of the overqualified are also overskilled, so that a third of the overall incidence of overqualification falls into the least satisfactory category. A much less-researched form of mismatch is skill obsolescence, under which skills depreciate over time as the result of either changes in technology or the effects of the aging of the worker. According to a 2012 CEDEFOP pilot survey in four countries (Finland, Germany, Hungary, and the Netherlands), skill obsolescence affects 12% of workers.

There are measurement issues arising in relation to these estimates. The assumption is made that there is a particular educational requirement for a particular job. This ignores the possibility that one form of human capital may be substitutable for another. Thus, while undereducated workers may lack education, they may make up for this by having more experience on the job. The estimates are also dependent on the availability of appropriate data sets. Three types of measurement have been conducted in relation to qualifications mismatch:

1. Systematic job evaluation may be utilized to determine the precise level of qualifications required to perform a particular job, which is sometimes referred to as an objective measure. This is not commonly used, however, perhaps because the appropriate educational level may change as the nature of jobs changes over time, and the required educational level may lag behind.
2. Worker self-assessment, often referred to as a subjective measure, depends on the nature of the questions asked, such as what level of education is required to obtain the job you currently hold, or what level of education is required to perform the job you hold? If the answer to the first question implies a higher level of education than the answer to the second question, this is consistent with credentialism on the part of the employer, which might occur in a slack labor market with plenty of job applicants. Credentialism can be defined as a situation in which the level of education required to *obtain* a job exceeds the level of education required to *perform* the job adequately. This rests on a belief held by the employer that the possession of certificates and diplomas implies higher productivity on the part of the employee (sometimes referred to as a sheepskin effect).
3. Many data sets do not contain a direct question on qualifications mismatch in which case reliance has to be placed on the so-called empirical method. In such cases qualifications mismatch is frequently measured as the situation in which the level of education is more than one standard deviation above or below the mean, which will only pick up cases where mismatch is substantial and therefore cannot be compared with the two measures above. Further, as the degree of overeducation and undereducation is often asymmetric (as in **Table 1**), it is more appropriate to use deviations from the mode rather than the mean. Thus, the use of the mode is increasingly being adopted.

A number of studies have attempted to measure the correlation among the three measures above and find it to be low, with different people being identified as mismatched according to the measure used. Thus, Verhaest and Omey (2006) compared the reliability of five different measures of overeducation on the basis of encompassing tests and concluded that the objective measure and a subjective measure based on the level of education needed to do the job should always be preferred to both empirical methods based on mean or modal education and a subjective measure based on the level of education needed to get the job. Studies rarely consider the severity of mismatch – largely due to the lack of data – but a degree holder working in a job for which a high-school certificate is acceptable should not cause as much concern as a degree holder working in an unskilled job.

The equivalent of the empirical method for measuring qualifications mismatch is not available for skills mismatch, and analysis is totally dependent on direct questions being asked of employees in surveys, such as 'to what extent are you able to utilize the skills and abilities you possess in your current job?' Answers are often given on a seven-point scale. Desjardins and Rubenson (2011) suggest that although qualifications mismatch has the advantage of being easier to measure and is broader in its coverage of skills, it also has the disadvantage of being less precise because it does not allow for differences in the quality of similar qualifications, such as degree classification or the reputation of the institution where the qualification was obtained. Further, no allowance is made for the possibility that there may be skill gain or loss after the date at which the qualification was obtained. Skills obsolescence can arise for a number of reasons, which means that it may not be possible to capture it in a single question. Workers may be asked if there are any skills that they previously possessed which are no longer required; or are there any new skills in the current job that have emerged, but which they do not possess; or whether they consider that their ability to perform their current job has diminished over time.

Relationship of Mismatch Models to Existing Theories

The naïve Mincer human capital model is basically a supply-driven model which implies that earnings are determined just by the personal characteristics of the worker, so that precisely where an individual is employed is immaterial to the level of earnings:

$$\text{Log } W_i = a + bS_i + cX_i + \mathrm{d}X_i^2 + e_i \qquad [2]$$

where W denotes the level of wages, a the constant term, X the years of experience, e the error term, and subscript i the ith individual.

At the other extreme is the Thurow (1975) job competition model which assumes that productivity is determined

exclusively by the job, rather than the worker, with superior personal characteristics simply serving to push the job applicant to the front of the job queue. Thus, in this demand-driven model, all workers within a particular job will be paid the same regardless of their qualifications. Thus,

$$\text{Log } W_i = a + b_1 q^r + e \qquad [3]$$

where q^r is the *minimum* qualifications required to obtain the job.

Between these two extreme models lies the Sattinger (1993) job assignment model, which is based on the belief that there is an allocation problem in the assignment of heterogeneous workers to jobs which vary in their complexity. Let S_i equal the extent to which skill i is required by a particular employer, and t_i is the extent to which this is possessed by particular employees. Then, on the demand side of the labor-market employers will collectively specify a frequency distribution M (s_1, s_2, … , s_m) of the number of employees they require at various skill levels. Similarly, on the supply side of the labor market, potential employees will be available with a frequency distribution of skills N (t_1, t_2, …, t_n). Therefore, if

$$M(s_1, s_2, \ldots, s_m) \neq N(t_1, t_2, \ldots, t_n) \qquad [4]$$

overeducation or undereducation will ensue, and might well be a persistent problem if both distributions are subject to continual change, which seems likely in a dynamic economy. In fact, the assignment model encompasses both the human capital model and the job competition model as special cases. Imposing an appropriate set of restrictions and using an F test on the residual sum of squares, both the human capital and job competition models can be rejected in favor of the encompassing job assignment model on the basis of different data sets (see Hartog, 1986; Hartog and Oosterbeek, 1988; Sloane et al., 1999).

A more general model in the spirit of the job assignment model, which has been used by a large number of economists subsequently, was implemented by Duncan and Hoffman (1981) and is frequently referred to as the ORU (over-, required- and under-education) model. This decomposes qualifications into those required to do the job (q^r), those surplus to requirements (q^s), and those which are lower than currently required (q^u). Thus, in this case

$$\text{Log } W_i = b_0 + b_1 q^r + b_2 q^s + b_3 q^u + e \qquad [5]$$

With q^r set as the default, the expected sign on q^s is positive, and that on q^u negative. According to the naïve Mincer human capital model, it must be that $b_1 = b_2 = b_3$ and returns are not influenced by the circumstances of employment. In contrast, in the case of the job competition model it must be that $b_2 = b_3 = 0$, as only required education determines pay in this case. It should be noted that mismatch is only a serious problem in the long run if the relative supplies of different types of education do not affect the skill composition of final demand. This would amount to there being fixed skill requirements, so that employers do not respond by changing their methods of production to accommodate the changed supply conditions. The ORU approach has been criticized by Leuven and Oosterbeek (2011) on the grounds that the model may be subject to both omitted variable bias and measurement error, neither of which is satisfactorily dealt with in much of the literature.

Brief mention may be made of two alternative approaches to the above. First, Sicherman and Galor's theory of career mobility (1990) suggests that individuals may accept a lower-level job in order to invest in a form of training and recoup a return through accelerated promotion in the future. In this context, mismatch is a purely temporary phenomenon. Second, Frank's theory of differential overqualification (1978) is based on the proposition that for married couples the search for a pair of jobs will be constrained geographically, and it will rarely be possible to optimize the position of both partners. Under the male chauvinist model, the husband will optimize his employment and the wife will be constrained either as a tied stayer in the current location or a tied mover in a new location, so that married women may face a greater degree of overeducation than do men or single women.

Causes of Mismatch

A key issue is to what extent mismatch is explained by heterogeneity in terms of labor quality, or by workers trading off attachment to jobs which do not require their level of qualification for positive job attributes, such as an easier pace of work, locational advantages, or preferred hours. Either of these possibilities would not imply that mismatch must represent a form of market failure. A number of studies have found that those with better degree classifications and from more established universities are less likely to be overeducated. Also, those graduating in more professional disciplines such as engineering or law are less likely to be overeducated than are those with more general degrees such as arts. On the demand side, the higher the occupation or the greater the size of firm the greater the probability of a match. One way to cast some light on these issues is to disaggregate the overeducation variable by distinguishing between those who are overeducated but have high job satisfaction and those who are overeducated but have low job satisfaction. Thus, Chevalier (2003) and Chevalier and Lindley (2009) classify the former as apparent overeducation, and the latter as genuine overeducation. Compared to matched graduates the apparently overeducated were found to have a wage penalty of 7% and the genuinely overeducated a penalty of 23%. Including various measures of skill reduced the penalty by between 2 and 5 percentage points, but did not eliminate it. A similar approach was adopted by Green and Zhu (2010) who distinguish between real and formal overeducation according to whether or not overeducation is accompanied by skill underutilization. They find that those in the real overeducation category suffer from higher wage penalties than do those in the formal overeducation category; and as well, they experience considerably lower job satisfaction.

Individual characteristics such as membership of discriminated against groups such as the young, the elderly, females, ethnic minorities, and the disabled may give rise to mismatch. Young workers may be particularly prone to mismatch as new entrants into the labor market, since they lack work experience; older workers may suffer from mismatch as a consequence of skill obsolescence, as outlined above. Several studies have confirmed that mismatch is greater for members of minority groups and immigrants. There is no strong evidence, however,

to support the suggestion that women are more likely than men to suffer from mismatch. The case of mismatch in the context of workers with disability was investigated by Jones et al. (2014) who do not find any relationship between work-limiting disability and overskilling, but find a positive relationship between work-limiting disability and overeducation.

There may be cohort effects if individuals qualify for entry into the labor market at a time when there are more graduates or when the market is depressed, so that there is an excess supply of qualified applicants. This may cause some to accept lower-level jobs than they are qualified for and, in turn, force others at that level to take a similar step, so that there is a bumping down phenomenon in which appropriately qualified workers are forced out of current jobs by those with higher qualifications, and are then forced into lower-level jobs or out of employment altogether.

Consequences of Mismatch

A large number of studies have been undertaken using cross-sectional data and have found that labor-market mismatch – whether in the form of qualifications or skills – is associated with negative labor-market outcomes in the form of lower wages, reduced job satisfaction, and higher labor turnover. Sicherman (1991) reported two stylized facts in relation to wages. First, overeducated workers are paid less than if they were matched, but more than their matched coworkers so that while there is a wage penalty for employees, employers pay a premium for employing them. Second, in contrast, undereducated workers are paid more than if they were matched, but less than their matched coworkers. They, therefore, benefit by being paid more than if they were in a job commensurate with their qualifications, and there is an incentive to remain in their current employment. These results have been confirmed in a large number of subsequent studies, but virtually all of these are based on cross-sectional data and, therefore, may be biased due to the problem of unobserved individual heterogeneity. Sattinger and Hartog (2013) and Sattinger (2012) show – while making some relatively mild assumptions – that the above outcome can be explained by Nash bargaining between workers and employers.

An important question is why do employers hire overeducated workers and pay them a premium wage? Not a great deal is known about this because we lack employer surveys with relevant questions; according to the human capital approach, however, higher earnings must reflect higher productivity. In imperfect markets, however, the link between wages and productivity is imprecise with firms possibly obtaining a rent from the services of their employees. Few attempts have been made to measure this directly using a production-function approach. One exception is Tsang (1987), who used a Cobb–Douglas production function in a case study of the Bell Corporation in the United States and found evidence of a negative productivity effect. In contrast, a positive effect was found by Kampelmann and Rycx (2012), using a linked employer–employee panel for Belgium, covering the period 1999–2006. They measure value added per worker and control for simultaneity, time invariant workplace characteristics, cohort effects, and dynamics. Based on the ORU specification, it appears that a higher level of required education has a significant positive effect on firm productivity, and additional years of overeducation have a similar effect. However, additional years of undereducation among young workers have the reverse effect. There is no relationship with profits, suggesting the wage and productivity effects cancel out one another.

The most common methodology used in applied econometrics for controlling for potential bias caused by unobserved individual heterogeneity is the use of panel data, which consists of time series of cross-section data. Earlier examples of this literature are Mundlak (1978) and Deaton (1985), with later comprehensive expositions found in Hsiao (2003) and Arellano (2003). Examples of applications in the area of mismatch include Bauer (2002) using the German Socio-Economic Panel, Tsai (2010), using the U.S. Panel of Income Dynamics, Quintini (2011b), using the European Community Household Panel, which covered the period 1994–2001, and Mavromaras et al. (2013a) using the Household, Income and Labour Dynamics in Australia (HILDA) panel data. Each of them finds that the mismatch wage penalty is much reduced when controlling for unobserved individual heterogeneity. The last of these is particularly revealing, as the authors analyze mismatched workers according to whether they are matched, overeducated, overskilled, or a combination of the two. They present two types of estimation – pooled cross-section, as a comparison point with the earlier literature, and random effects probit with Mundlak corrections. They find that there is a significant pay penalty in their male sample only for those who are both overskilled and overeducated. Further, job satisfaction is not reduced by being overeducated, but is clearly reduced by overskilling, whether on its own or when jointly present with overeducation. With the exception of the case where overskilling and overeducation are present jointly, mismatch has no significant effect on the quit rate. These results overturn much of the previous literature, but without similar analyses for other countries we cannot say whether they apply outside Australia. Quintini (2011b) explores the effect on mismatch of involuntary separations at different points of the business cycle. When the unemployment rate is in line with its medium-term average, losing one's job because of a business closure increases the likelihood of overqualification in the next job by 15% compared to quitting, but if the unemployment rate becomes twice as large as its average rate this effect increases to 35%. She does not, however, interact overqualification and overskilling as in the Mavromaras et al. (2013a) study.

The extent to which mismatch is a temporary phenomenon is important from the policy point of view, but one on which there is no consensus. Mavromaras and McGuinness (2012) and Mavromaras et al. (2013b) use a random effects dynamic probit model to estimate the persistence of overskilling and the effect of overskilling dynamics on wages, using the HILDA survey data. They show that being overskilled is associated with lower wages and more overskilling at the population level, and that becoming overskilled causes lower wages and a higher probability of future overskilling at the individual level. They find that overskilling is highly persistent in a manner that is inversely related to educational level. Furthermore, the wage penalties are also persistent, which magnifies

the scarring effects of overskilling. Where exits from overskilling do occur, Quintini (2011b) suggests that they are most likely to derive from improvements in the match between workers and jobs through either a job change or job upgrading, such as by giving the worker more responsibilities. In contrast, overqualified individuals can only become well-matched by changing jobs.

Few studies have examined the relationship between skill mismatch and the business cycle, mainly because of a lack of a sufficiently long series of panel micro data (CEDEFOP, 2010). The business cycle will influence skill mismatch through changing the demand for skills, and the return to well-matched skills will be increased in upturns and reduced in downturns. It is possible that the response of the labor market will feed back into the business cycle, especially through skill hoarding and training responses. The distinction between firm or sector human capital and general human capital becomes pertinent, as it impacts on the willingness of firms and individuals to pay for training. The social opportunity cost to the state of contributing toward the cost of training can be considerably reduced during a recession, making the question of who pays for training cycle-dependent.

Policy Implications

There is a lot of unobserved individual heterogeneity which is revealed when panel estimation is utilized. Overeducation on its own appears to have few negative effects suggesting that for many the state of overeducation is a choice variable, in which individuals trade-off being matched for compensating differences which leave them satisfied. Policy should focus more on skills mismatch which does appear to have negative consequences. This should qualify statements such as the assertion made by a recent European Union report (2012, p. 351) on skills mismatch to the effect that "skill mismatch negatively affects economic competitiveness and growth, increases unemployment, undermines social inclusion, and generates significant economic and social costs." While this may be the case for skills mismatch, it is less obviously so for qualifications mismatch, though even here there are questions of whether the education received is a good investment for the state. As Quintini (2011a) notes, very few studies mention the policy implications of their findings, but where they do, suggestions include a better match between what is delivered through the education system and the requirements of the labor market, including a better careers guidance service, and extended training and retraining systems, which deal both with the needs of the unemployed and those subject to skill obsolescence.

Missing Data

Abstract

The problem of missing data is ubiquitous in the social and behavioral sciences. We begin by distinguishing between the pattern of missing data and the mechanism that creates the missing data. Then we consider common, but limited, approaches: complete-case analysis, nonresponse weighting, and single imputation. We then discuss more principled methods, including maximum likelihood and multiple imputation.

Introduction

Missing values arise in social science data for many reasons. Some examples follow. In longitudinal studies, subjects often drop out prior to the end of the study (*attrition*). In many surveys, some individuals provide no information because of noncontact or refusal to respond (*unit* nonresponse). Others are contacted but provide only some information (*item* nonresponse). Information about a variable is partially recorded; a common example in social science occurs when times to an event (death, finding a job) are being recorded, and the event has not taken place for some individuals when the study is terminated; the time for such a subject is known to be greater than that corresponding to the latest time of observation, but the actual time is unknown (*right censoring*). In other situations it is known that the time to an event lies in an interval; for example, in a longitudinal study of employment, it may be established that the event of finding a job took place some time between two interviews (*interval censoring*). Often indices are constructed by summing values of particular items, some of which may be missing.

Missing data can arise by design. For example, suppose one objective in a study of obesity is to estimate the distribution of a measure Y_1 of body fat in the population, and correlate it with other factors. Suppose Y_1 is expensive to measure but a proxy measure Y_2, such as body mass index, which is a function of height and weight, is inexpensive to measure. Then it may be useful to measure Y_2 and covariates, X, for a large sample and Y_1, Y_2, and X for a smaller subsample. The subsample allows predictions of the missing values of Y_1 to be generated for the larger sample, yielding more efficient estimates of quantities involving Y_1 than are possible from the subsample alone.

The most important step in dealing with missing data is to try to avoid having them by careful design and data collection (e.g., National Research Council, 2010). Because data are likely to be missing in any case, however, it is important to try to collect covariates that are predictive of the missing values, so that an adequate adjustment can be made. In addition, the process that leads to missing values should be assessed during the collection of data if possible (Little, 1995), because this information helps to model the missing-data mechanism when an adjustment for the missing values is performed.

Three major approaches to the analysis of missing data can be distinguished: (1) Discard incomplete cases and analyze the remainder (complete-case (CC) analysis), as discussed in the section 'Complete-Case and Weighting Methods'; (2) impute or fill in one number for each missing value and then analyze the filled-in data (single imputation), as discussed in the section 'Single Imputation'; and (3) analyze the incomplete data by a method that does not require a complete (that is, a rectangular) dataset. In particular, we focus in sections 'Multiple Imputation,' 'Maximum Likelihood for Ignorable Models,' 'Maximum Likelihood for Nonignorable Models,' and 'Bayesian Simulation Methods' on powerful likelihood-based methods, specifically ML and Bayesian simulation (*see* Bayesian Statistics). The latter is closely related to multiple imputation (MI) (Rubin, 2004), an extension of single imputation that allows uncertainty in the imputations to be reflected appropriately in the analysis, as discussed in the section 'Multiple Imputation.'

A basic assumption in all our methods is that missingness of a particular value hides a true underlying value that is meaningful for analysis, which may seem obvious but is not always the case. For example, consider a longitudinal analysis of employment; for subjects who leave the study because they move to a different location, it makes sense to consider employment history after relocation as missing, whereas for subjects who die during the course of the study, it is not reasonable to consider employment history after time of death as missing. Rather it is preferable to restrict the analysis of employment to individuals who are alive. More complex missing-data problems arise when individuals leave a study for unknown reasons, which may include relocation or death.

Pattern and Mechanism of Missing Data

The *pattern* of the missing data refers to indicators for which values in the dataset are observed and which are missing. Specifically, let $Y = (y_{ij})$ denote an $(n \times p)$ rectangular dataset without missing values, with ith row $y_i = (y_{i1}, \ldots, y_{ip})$, where y_{ij} is the value of variable Y_j for subject i. With missing values, the pattern of missing data is defined by the *response indicator matrix* $R = (r_{ij})$, such that $r_{ij} = 1$ if y_{ij} is observed and $r_{ij} = 0$ if y_{ij} is missing; $1 - r_{ij}$ is the missing-data indicator for y_{ij}.

Some methods for handling missing data apply to any pattern of missing data, whereas other methods assume

a special pattern. A simple special pattern is *univariate* nonresponse, where missingness is confined to a single variable. Another example is *monotone* missing data, where the variables can be arranged so that $Y_{j+1}, \ldots, Y_p$ are missing for all subjects where Y_j is missing, for all $j = 1, \ldots, p-1$. The result is a 'staircase' pattern, where all variables and units to the left of the broken line forming the generally irregular staircase are observed, and all to the right are missing. This pattern arises in longitudinal data subject to attrition, where once a person drops out, no more data are observed for that person.

The missing-data mechanism addresses the reasons why values are missing, and in particular whether these reasons relate to values in the dataset. For example, subjects involved in a longitudinal intervention may be more likely to drop out of a study because they feel a treatment was ineffective, which might be related to a poor value of an outcome measure. Rubin (1976) treated R as a random matrix and characterized the missing-data mechanism by the conditional distribution of R given Y, say $f(R|Y, \phi)$, where ϕ denotes unknown parameters. When missingness does not depend on the values of the data Y, missing or observed, that is,

$$f(R|Y, \phi) = f(R|\phi) \quad \text{for all } Y, \phi \frac{1}{2}$$

the missing-data mechanism is called missing completely at random (MCAR). MCAR does not mean that the pattern itself is random, but rather that missingness does not depend on any data values. An MCAR mechanism is plausible in some planned missing-data designs, but is a strong and often unrealistic assumption, especially when missing data do not occur by design, because missingness often does depend on values of variables.

Using a notation that can be made more precise, let Y_{obs} denote the observed components of Y and let Y_{mis} denote the missing components of Y. A less-restrictive assumption is that missingness depends only on values Y_{obs} that are observed and not on values Y_{mis} that are missing. That is,

$$f(R|Y, \phi) = f(R|Y_{\text{obs}}, \phi) \quad \text{for all } Y_{\text{mis}}, \phi \qquad [1]$$

The missing data are then called missing at random (MAR) at the observed values of R and Y_{obs}. Many methods for handling missing data assume the mechanism is MCAR, and yield biased estimates when the data are not MCAR. Better methods only assume MAR or some other explicitly defined mechanism.

Complete-Case and Weighting Methods

A common and simple method is CC analysis, also known as *listwise* deletion, where units with any missing values are discarded and standard analysis methods are applied to the remaining complete cases. In many statistical packages this is the default analysis. Valid (but often suboptimal) repeated-sampling inferences are obtained when the missing data are MCAR, because then the complete cases are a random subsample of the original sample with respect to all variables. However, even under MCAR, CC analysis results in the loss of the information in the incomplete cases, which may be substantial, particularly when the number of variables is large.

A serious problem with dropping incomplete cases is that the complete cases are often a biased sample. The size of the resulting bias depends on the degree of deviation from MCAR, the amount of missing data, and the specific analysis being conducted. For example, inferences about means are subject to bias if the missingness mechanism deviates from MCAR, but inference about regression coefficients is valid (although often inefficient) if the missingness mechanism depends on covariates but not on outcomes. In sample surveys, this issue motivates strenuous attempts to limit unit nonresponse through multiple follow-ups, and surveys with high rates of unit nonresponse (say 30% or more) are often considered unreliable for making inferences to the whole population.

A modification of CC analysis, commonly used to handle unit nonresponse in surveys, is inverse probability weighting (IPW), which weights respondents by the inverse of an estimate of the probability of response. In particular, when estimating a population mean, the sample mean is replaced by the weighted mean. A simple approach for creating weights is to form adjustment cells (also called subclasses) based on background variables measured for respondents and nonrespondents; for unit nonresponse adjustment, these are often based on geographical areas or groupings of similar areas based on aggregate socioeconomic data. All nonrespondents are assigned zero weight and the nonresponse weight for all respondents in an adjustment cell is then the inverse of the response rate in that cell. This method removes the component of nonresponse bias attributable to differential nonresponse rates across the adjustment cells, and eliminates bias if, within each adjustment cell, respondents can be regarded as a random subsample of the original sample within that cell (i.e., the data are MCAR within each adjustment cell).

With more extensive background information, a useful alternative approach is *response propensity* stratification, where (1) the indicator for unit nonresponse is regressed on the background variables, using the combined data for respondents and nonrespondents, using a method such as logistic regression appropriate for a binary outcome; (2) a predicted response probability is computed for each respondent based on the regression in (1); and (3) adjustment cells are formed based on a categorized version of the predicted response probability. Theory (Rosenbaum and Rubin, 1983) suggests that this is an effective method for removing nonresponse bias attributable to the background variables used to form the adjustment cells when unit nonresponse is MAR.

Although IPW can be useful for reducing nonresponse bias, it does have serious limitations. First, information in the incomplete cases is still discarded, so the method is generally inefficient; weighted estimates can have unacceptably high variance, especially when outlying values of a variable are given large weights. For modifications of the IPWs to increase efficiency, see for example Cao et al. (2009).

Variance estimation for weighted estimates should take into account uncertainty in the estimated weights (*see* Estimation: Point and Interval). Approaches include Taylor series expansion (Robins et al., 1995) or computing bootstrap standard errors – but in order to reflect all the uncertainty, the weights have to be recalculated for each bootstrap sample (Little and Rubin, 2002: Chapter 5).

Single Imputation

Methods that impute or fill in the missing values have the advantage that, unlike CC or IPW analysis, observed values in the incomplete cases are retained. A simple version imputes missing values of a variable by its unconditional sample mean based on the observed data. This method can yield satisfactory point estimates of means and totals under MCAR, but it yields inconsistent estimates of other estimands, such as variances, covariance matrices, or regression coefficients, and standard errors based on the filled-in data are systematically underestimated (Little and Rubin, 2002: Chapter 3). Thus it cannot be recommended in any generality.

An improvement is *conditional mean* imputation, in which missing values for a unit are replaced by estimates of their conditional mean given the values of observed variables for that unit. For example, in the case of univariate nonresponse with $Y_1, \ldots, Y_{p-1}$ fully observed and Y_p sometimes missing, one approach is to classify units into cells based on similar values of observed variables and then to impute missing values of Y_p by the within-cell mean from the complete units in that cell. A more general approach is to regress Y_p on $Y_1, \ldots, Y_{p-1}$ using the complete units and then impute the missing values of Y_p using the predictions from the regression (*regression imputation*). For a general pattern of missing data, the missing values for each unit can be imputed from the regression of the missing variables on the observed variables, computed using the set of complete units. Iterative versions of this method lead (with some important adjustments) to ML estimates under multivariate normality (Little and Rubin, 2002: Chapter 8).

Imputations can be used to improve the efficiency of IPW estimates. In particular, augmented IPW (AIPW) estimates of the mean use a model to predict the missing values and then apply IPW to the residuals (Robins et al., 1994, 1995); this increases the efficiency of IPW if there are good predictors. These estimators afford some protection against misspecification of the prediction model for the missing values, and in particular are called *doubly robust*, in the sense that they are consistent for the target parameter if either the prediction model or the model for estimating the response propensities is correctly specified. There is some debate about the utility of this property in practice, because all models suffer from some degree of misspecification, and the approach can be nonrobust if neither model is correct (Kang and Schafer, 2007; Zhang and Little, 2011; Waernbaum, 2012). The penalized spline of propensity prediction (Zhang and Little, 2009) method estimates the response propensity and then models its relationship with the outcome using a penalized spline, including other predictors parametrically. This approach appears to perform well in simulations (Zhang and Little, 2011). For estimands other than means, AIPW methods can be applied to inferences based on generalized estimating equations with missing data – see, for example, Tsiatis (2006).

Although conditional mean imputation incorporates information from the observed variables and under MAR yields best predictions of the missing values in the sense of mean squared error, it leads to distorted estimates of quantities that are not linear in the data, such as percentiles, correlations, and other measures of association, variances and other measures of variability. A way to address this problem is to use random draws rather than best predictions to preserve the distribution of variables in the filled-in dataset. An example is *stochastic regression* imputation, in which each missing value is replaced by its regression prediction plus a random error based on the estimated residual variance.

Hot-deck methods impute actual values observed in the dataset. A simple approach creates adjustment cells based on variables observed for respondents and nonrespondents and then imputes nonrespondent values using a randomly selected respondent value in the same cell. This method requires categorizing continuous observed variables, and is less satisfactory with extensive variables, because the number of adjustment cells becomes large. A more general approach to hot-deck imputation matches nonrespondents and respondents using a distance function based on the variables observed for both types of units. For example, *predictive mean matching* (Rubin, 1986; Little, 1988b) matches units with similar predicted means from a regression of the missing variable on observed variables. This method is somewhat robust to misspecification of the regression model used to create the matching metric. These methods, and extensions to handle general patterns of missing data, are reviewed in Andridge and Little (2010).

The imputation methods discussed so far assume the missing data are MAR. In contrast, models that are missing not at random (MNAR) assert that even if a respondent and a nonrespondent to Y_p appear identical with respect to observed variables $Y_1, \ldots, Y_{p-1}$, their Y_p values differ systematically. Lillard et al. (1986), for example, discussed MNAR imputation models for missing Current Population Survey data. It is also possible to create an MNAR hot-deck procedure; for example, respondents' values that are to be imputed to nonrespondents could be multiplied by an inflation or deflation factor that depends on the variables that are observed. A crucial point about the use of MNAR models is that there is rarely direct evidence in the data to address the validity of their underlying assumptions. Thus, whenever MNAR models are being considered, it is prudent to consider several MNAR models and explore the sensitivity of analyses to the choice of model (Rubin, 1977; Little and Wang, 1996; National Research Council, 2010; Liublinska and Rubin, 2014).

Multiple Imputation

A single imputed value cannot represent the uncertainty about which value to impute, so analyses that treat imputed values just like observed values generally underestimate uncertainty, even if nonresponse is modeled correctly and random imputations are created. Large-sample results show that for simple situations with 30% of the information missing, single imputation under the correct model results in nominal 90% confidence intervals having actual coverages below 80%. The inaccuracy of nominal levels is even more extreme in multiparameter testing problems (Rubin, 2004: Chapter 4).

A modification of imputation that fixes this problem is MI (Rubin, 1987, 2004). Instead of imputing a single set of draws for the missing values, a set of M (say $M = 5$) datasets are created, each containing different sets of draws of the missing values from their predictive distribution. We then apply the

standard complete-data analysis to each of the M datasets and combine the results in a simple way. In particular for scalar estimands, the MI estimate is the average of the estimates from the M datasets, and the sampling variance of the estimate is the average of the sampling variances from the five datasets plus $1+M^{-1}$ times the sample variance of the estimates over the M datasets; the factor $1+M^{-1}$ is a small-M correction; the last quantity here estimates the contribution to the variance from imputation uncertainty, missed (i.e., set to zero) by single imputation methods. Another benefit of MI is that averaging over datasets results in more efficient point estimates than does single random imputation. Often MI is not much more difficult than doing a single imputation – the additional computing from repeating an analysis M times is not a major burden and methods for combining inferences are straightforward. Most of the work is in generating good posterior predictive distributions for the missing values, which is needed for consistent point estimation in any case.

An important refinement is to create each of the imputed datasets using a different draw of the estimated parameters, thereby reflecting uncertainty in the parameter estimates. This form of MI is called *proper* (Rubin, 2004: Chapter 4).

Maximum Likelihood for Ignorable Models

There are statistical methods that let us analyze a nonrectangular dataset without having to impute the missing values. In particular, ML avoids imputation by formulating a statistical model and basing inference on the likelihood function of the incomplete data. Define Y and R as before, and fully observed fixed covariates are implicit in our notation. The data and missing-data mechanism are modeled in terms of a joint distribution for Y and R. *Selection models* specify this distribution as

$$f(Y,R|\theta,\phi)=f(Y|\theta)f(R|Y,\phi) \qquad [2]$$

where $f(Y|\theta)$ is the model for Y in the absence of missing values, such as the multivariate normal; $f(R|Y,\phi)$ is the model for the missing-data mechanism, such as the multinomial logit or probit model; and θ and ϕ are unknown parameters. The likelihood of θ, ϕ given the data Y_{obs}, R is then proportional to the density of Y_{obs}, R regarded as a function of the parameters θ, ϕ, and is obtained by integrating the density in eqn [2] over the missing data Y_{mis}, that is

$$L_{\text{full}}(\theta,\phi|Y_{\text{obs}},R)=\text{const.}\times\int f(Y,R|\theta,\phi)\mathrm{d}Y_{\text{mis}} \qquad [3]$$

The likelihood of θ *ignoring the missing-data mechanism* is obtained by integrating the marginal distribution of Y over the missing data, that is

$$L_{\text{ign}}(\theta|Y_{\text{obs}})=\text{const.}\times\int f(Y|\theta)\mathrm{d}Y_{\text{mis}} \qquad [4]$$

This likelihood is easier to work with than eqn [3], because it is typically more tractable computationally, and more importantly, avoids the need to specify a model for the missing-data mechanism, about which little is known in many situations. Hence it is important to determine when valid likelihood inferences are obtained from eqn [4] instead of the full likelihood eqn [3]. Rubin (1976) showed that valid likelihood-based inferences about θ are obtained from eqn [3] when the missing data are MAR, i.e., eqn [1], and θ and ψ are distinct in the sense that they take values in disjoint parameter spaces; the missing-data mechanism is then called *ignorable* for likelihood inferences. Large-sample inferences about θ based on an ignorable model are based on ML theory, which shows that under regularity conditions,

$$\theta-\widehat{\theta}\sim N_k(0,C) \qquad [5]$$

where $\widehat{\theta}$ is the value of θ that maximizes eqn [4], and $N_k(0,C)$ is the k-variate normal distribution with mean zero and covariance matrix C given by the inverse of an information matrix; for example, $C=I^{-1}(\widehat{\theta})$ where I is the observed information matrix given by $I(\theta)=-\partial^2\log L(\theta|Y_{\text{obs}})/\partial\theta\partial\theta^T$, or $C=J^{-1}(\widehat{\theta})$, where $J(\theta)$ is the expected value of $I(\theta)$. As in Little and Rubin, 2002: Chapter 6, eqn [5] is written to be open to a frequentist interpretation if $\widehat{\theta}$ is regarded as random and θ fixed, or a Bayesian interpretation if θ is regarded as random and $\widehat{\theta}$ fixed. Thus if the missing data are MAR, the likelihood approach reduces to developing a suitable model for the data and computing $\widehat{\theta}$ and C.

In many problems, maximization of the likelihood to compute $\widehat{\theta}$ requires numerical methods. These methods include standard optimization methods such as Newton–Raphson or scoring, or the Expectation-Maximization (EM) algorithm (Dempster et al., 1977) or one of its extensions; theory and numerous applications of EM can be found in Meng and Pedlow (1992), Schafer (1997), McLachlan and Krishnan (1997), and Little and Rubin (2002: Part II). Examples include multivariate normal data with a general pattern of missing values and the related problem of multivariate linear regression with missing data; robust inference based on multivariate t models; loglinear models for multiway contingency tables with missing data; and the general location model for mixtures of continuous and categorical variables, which yields ML algorithms for logistic regression with missing covariates. Another common software implementation of ML is to repeated-measures models with missing outcome variables.

Maximum Likelihood for Nonignorable Models

Nonignorable, non-MAR models apply when missingness depends on the missing values (see the section 'Pattern and Mechanism of Missing Data'). A correct likelihood analysis must be based on the full likelihood from a model for the joint distribution of Y and R. The standard likelihood asymptotics apply to nonignorable models, and computational tools such as EM also apply to this more general class of models (see Little and Rubin, 2002: Chapter 15). However, often information needed to estimate all the parameters is very limited, and estimates are sensitive to misspecification of the model. Often a sensitivity analysis is needed to see how much the answers change for various assumptions about the missing-data mechanism.

Pattern-mixture models are particularly useful here, and specify

$$f(Y,R/\pi,\psi)=f(Y/X,\psi)f(R/X,\pi) \qquad [6]$$

That is, models for Y given X for each pattern of missing data, where ψ and π are unknown distinct parameters, and now the distribution of Y is conditioned on the missing-data pattern, R (Rubin, 1977; Little, 1993).

Although most of the literature on missing data has concerned selection models that specify $f(Y|\theta)$ and $f(R|Y, \phi)$ as in eqn [2], pattern-mixture models can also provide inferences for parameter θ of the complete-data distribution, by expressing it as functions of the pattern-mixture model parameters ψ and π. Pattern-mixture models of the form of eqn [6] are simpler to fit, and often have a more straightforward practical interpretation (National Research Council, 2010; Giusti and Little, 2011; Carpenter and Kenward, 2013).

Heitjan and Rubin (1991) and Heitjan (1994) extend the formulation of missing-data problems via the joint distribution of Y and M to more general incomplete data problems involving coarsened data. The idea is to replace the binary missing-data indicators by coarsening variables that map the γ_{ij} values to coarsened (e.g., rounded) versions. Full and ignorable likelihoods can be defined for this more general setting. This theory provides a bridge between missing-data theory and theories of censoring in the survival analysis literature. The EM algorithm can be applied to such models by including the missing-data (or coarsening) indicator in the complete-data likelihood.

Bayesian Simulation Methods

ML is most useful when sample sizes are large, because then the log-likelihood is nearly quadratic and can be summarized well using the ML estimate of θ and its large-sample variance–covariance matrix. When sample sizes are small, a useful alternative approach is to include a prior distribution for the parameters and compute the posterior distribution of the parameters of interest. For ignorable models this is

$$p(\theta/Y_{\text{obs}}|, R) \equiv p(\theta/Y_{\text{obs}}) = \text{const.} \times p(\theta) \times f(Y_{\text{obs}}/\theta)$$

where $p(\theta)$ is the prior distribution of θ, and $f(Y_{\text{obs}}|\theta)$ is the density of the observed data given θ, as in eqn [3]. Because the posterior distribution rarely has a simple analytic form for incomplete data problems, iterative simulation methods such as data augmentation (Tanner and Wong, 1987) and the Gibbs sampler (Geman and Geman, 1984) are often used to generate draws of θ from the posterior distribution $p(\theta|Y_{\text{obs}}, R)$. The Gibbs sampler starts with an initial draw $\theta^{(0)}$ from an approximation to the posterior distribution of θ. Given a value $\theta^{(t)}$ of θ drawn at iteration t:

1. Draw $Y_{\text{mis}}^{(t+1)}$ with density $p(Y_{\text{mis}}|Y_{\text{obs}}, \theta^{(t)})$
2. Draw $\theta^{(t+1)}$ with density $p(\theta/Y_{\text{obs}}, Y_{\text{mis}}^{(t+1)})$

The procedure is motivated by the fact that the distributions in steps 1 and 2 are often much easier to draw from than the correct posterior distributions $p(Y_{\text{mis}}|Y_{\text{obs}})$ and $p(\theta|Y_{\text{obs}})$. Under mild regularity conditions, the iterative procedure can be shown in the limit to yield a draw from the joint posterior distribution of Y_{mis}, θ given Y_{obs}. The algorithm was termed chained data augmentation in Tanner (1991). This algorithm can be run independently K times to generate K draws from the approximate joint posterior distribution of θ and Y_{mis}.

Techniques for monitoring the convergence of such algorithms are discussed in a variety of places (e.g., Gelman et al., 2014: Chapter 11). Schafer (1997) developed data augmentation algorithms that use iterative Bayesian simulation to multiply – impute rectangular datasets with arbitrary patterns of missing values when the missing-data mechanism is ignorable. The methods are applicable when the rows of the complete-data matrix can be modeled as iid observations from the multivariate normal, multinomial loglinear, and general location models.

Overview

The advent of modern computing has made more principled methods of dealing with missing data practical (e.g., MI, Rubin, 1996). Such methods are finding their way into current commercial and free software. Schafer (1997), Van Buuren (2012), Carpenter and Kenward (2013), and the forthcoming third edition of Little and Rubin (2002) are sources to learn more about missing-data methodology.

Missing Girls: A Globalizing Issue

Christophe Z Guilmoto, IRD/CEPED, Paris, France

© 2015 Elsevier Ltd. All rights reserved.

Abstract

The recent 50 years have been characterized by an increasing proportion of men in the world's population. In addition to excess female mortality, this rise has been caused by the emergence of prenatal sex selection in Asia and Eastern Europe and has resulted in millions of missing girls. Among all preconditions such as the rise in sex selection technology and the rapid decline of fertility, the preference for sons is at the core of this demographic masculinization and only when it dies out will sex ratio come back to normalcy.

Women's long march toward greater gender equity has been a major landmark of the second half of the twentieth century. Educational expansion, urbanization, and rapid economic development have created many new opportunities for women around the world over the last few decades. Demographic change has in particular brought many benefits to women such as increasing longevity and survival of children, less frequent and more spaced childbearing, lower maternal mortality, and higher spatial mobility. Yet, aggregated population figures suggest on the contrary that women appear to have been subjected to the most systematic form of demographic discrimination over the last 50 years and that as a result, their relative share in the world's population has been regularly declining. Using recent demographic estimates (United Nations Population Division, 2013), we can observe the gradual increase in the sex ratio, which from 99.6 males per 100 females in 1950 to 101.6 in 2010. This growing proportion of men is a clear sign of a new gendered demography that has swept Asia and other parts of the world during the last decades.

The Growing Demographic Deficit of Women

The demographic records are clear: women have seen their proportion decline exactly when the world's population as a whole has recorded its most rapid historical increase following the onset of mortality decline during the twentieth century. The first explanation for their reduced share in the overall population is that women have not benefited from increased longevity as much as men. The apparent surplus of men is due in particular to various forms of discrimination causing excess female mortality, especially during childhood (United Nations, 2011). Another explanation is that female populations may be now affected by discrimination before their birth. In fact, both prenatal and postnatal mechanisms are at the source of this reduction of women's share in the population observed in many countries (Croll, 2000; Miller, 2001).

We should first remind readers that demography may appear ambivalent when it comes to sex ratios. On the one hand, more men are born than women and the sex ratio at birth (SRB) usually osculates around 105 male births per 100 female births (Chahnazarian, 1988). On the other hand, mortality is systemically favorable to women – from intrauterine period to old age. Women's life expectancy is often several years ahead of that of men, for both biological and behavioral reasons, and this differential causes the sex ratio to diminish regularly with age, starting at 105 males per female at birth to 100 during adulthood and even lower levels beyond 50 years of age. When mortality improves and fertility declines as happened almost everywhere over the last 100 years, the average age of the population increases as well as the proportion of women. But this is not what was observed in several countries because of the persistence of excess mortality among girls and the emergence of prenatal sex selection.

These two mechanisms have different social features (Guilmoto, 2012b). Gender-based excess mortality is an age-old feature of certain demographic régimes. Girls and women deemed of lesser value are in many ways disadvantaged, most commonly by being denied equal access to food, care, and other resources. Girls may be for instance vaccinated in lower proportions than their brothers, get a smaller share of food, or be taken less often to a clinic in case of illness. The most radical form of discrimination is female infanticide, a practice reported in the past in several regions of Asia. Other traces of excess female mortality are less easy to detect in the absence of reliable statistics, but they have been shown to prevail in many countries where mortality rates among women are suspiciously higher than expected. Yet, selective infanticide has now almost completely vanished and recent trends point to a gradual reduction in mortality differentials, with life expectancy now higher for women than men across the world.

The second mechanism relates to the elimination of unborn girls during pregnancy or even earlier during conception. It is never directly observable for want of reliable data on abortions by sex of the fetus. Yet, the SRB has unexpectedly increased in several countries over the last 30 years. It took years for demographers to make sense of this increasing share of male births and to fight off pseudo-biological theories such as the effects of hepatitis epidemics, conflict and stress, or unique physiological conditions in some countries. Yet, the fact that SRB in affected populations inevitably rise with birth order – as parents react to the absence of prior male births – confirms that this is not a biological mechanism, but on the contrary the result of a conscious demographic choice. In fact, apart from issues related to the quality of statistics, the only valid explanation for the relative absence of female births in several Asian countries lies in the emergence of prenatal elimination of female embryos and fetuses, with sex selective abortions

 http://dx.doi.org/10.1016/B978-0-08-097086-8.64065-5

playing a major role in these imbalances. (Early demographic studies can be found in Ramanamma and Bambawale (1980), Zeng et al. (1993), and Park and Cho (1995)).

Prenatal discrimination has indeed become the main driver of sex imbalances at birth over the last 30 years. **Table 1** presents recent statistics for a selection of countries where the proportion of male births is unduly high. This comparative table suggests that the issue of adverse SRB levels is not restricted to China and India: sex selection has become a more global phenomenon, with distinct manifestations in several regions of the world. The countries listed here form admittedly a mixed bag of nations with regard to their level of economic development, political systems, and cultural and religious traditions. We find for instance atheistic, Buddhists, Hindu, Sikh, Muslim, and Christian countries in our list. While Asia has long been blamed *en bloc* for prenatal discrimination, it appears that several affected countries are located in Eastern Europe and that conversely, many important Asian countries – from Iran to Japan and Indonesia – appear totally immune to mechanisms of prenatal sex selection.

In Asia, China and India are most prominent with their high SRB and these two countries are the first contributors to the world's imbalances (Attané and Guilmoto, 2007). The SRB has reached the extreme level of 120 male births per 100 female births in parts of India and China after 2000. India's average SRB is lower, but this is mostly due to the fact that many regions in the South or the East of the subcontinent do not practice prenatal sex selection at all. In Northwest India, especially from Punjab to Gujarat, the SRB can in fact be around 120 male births per 100 female births or higher. While lack of reliable estimates prevents us from concluding on Pakistan's probably high level of birth masculinity, the recent rise in the SRB in Vietnam during the last decade has been well documented. In addition, the almost normal SRB level observed today in South Korea conceals the rise observed during the 1980s, which briefly took birth masculinity to 115 male births per 100 female births before a subsequent decline. South Korea offers indeed the only illustration of a complete sex ratio transition, in which countries observe successively a temporary rise in their SRB and its decline (Guilmoto, 2009).

Table 1 Estimates of the sex ratio at birth in various countries around 2010

Country	*Sex ratio at birth*
East and Southeast Asia	
China	117.8
Singapore	107.5
South Korea	106.7
Vietnam	111.2
South Asia	
India	110.5
Pakistan	109.9
Caucasus	
Azerbaijan	116.5
Armenia	114.9
Georgia	111.8
Southeast Europe	
Albania	111.7
Kosovo	109.7
Montenegro	109.8

The normal sex ratio at birth is 105 male births per 100 female births.
Estimates from birth registration and demographic surveys.
Source: Guilmoto, C.Z., 2012b. Sex Imbalances at Birth. Current Trends, Consequences and Policy Implications, UNFPA, Bangkok and Guilmoto, C.Z., Duthé, G., 2013. Masculinization of births in Eastern Europe. Population & Societies 506, 1–4.

In Eastern Europe, two distinct regional clusters emerge (Guilmoto and Duthé, 2013). The first is located in the Southern Caucasus and includes three countries (Armenia, Azerbaijan, and Georgia) where birth masculinity is almost as high as in China. In spite of their proximity, these three countries have very distinct socioeconomic features as well as cultural and religious traditions and have been united only during the Soviet Union's era. Similarly, the other geographical cluster of high sex ratios at birth centers in Albania includes neighboring Kosovo, Montenegro, and Western Macedonia that were parts of the former Yugoslavia. These regions have not been part of the same polity since the dismantlement of the Ottoman Empire at the end of the nineteenth century.

To this list we should add a scattered set of diasporic populations, immigrants from sex-selecting regions found throughout the world in various countries and whose offspring sex ratios are biased in favor of male births (Dubuc and Coleman, 2007). This finding has been reported for instance among populations of Indian, Korean, and Chinese origin in North America and the United Kingdom. Albanian migrants in Italy and Greece also appear to beget more boys than biology would predict. While this phenomenon has little demographic impact in host countries, it shows that gender discrimination is not so much linked to the social and economic environment in origin countries than to the culture – mindset and attitudes – of people.

This initial geographical cluster suggests that adverse sex ratios tend to cluster in small regions and this is also true within countries as high values observed in India's Northwest and Vietnam's Red River Delta demonstrate. This obvious cultural dimension of gender discrimination goes deeper than ethnic, religious, or linguistic affiliation. For instance, the three countries of the South Caucasus have almost similar adverse levels of SRB in spite of deep religious, linguistic, and political variations. But there are also social variations, such as differences between rural and urban areas and across socioeconomic groups. Detailed studies show in particular that the richer strata tend initially to discriminate more strongly against female births than the poor. All these features help us understand why and how prenatal sex selection takes place (Guilmoto, 2012b).

The Causes of Gender Discrimination Regarding Offspring

Countries have often been reluctant to acknowledge the existence of prenatal sex selection, blaming faulty statistics or biological hazards for distorted sex ratios. It is true that prenatal sex selection tends to project an unsavory image of societies practicing it, but demographic evidence – from birth registration figures to census and survey results – has gradually been

shared to civil society and governments via academic and media reports. Once recognized, sex imbalances at birth tend to be attributed in each country to a specific set of local factors such as the dowry paid by parents of girls in India, strict family planning rules and Confucian precepts in East Asia, or economic crises and conflicts in Eastern Europe. Yet, the publicity received by these 'local narratives' of prenatal discrimination tends to obscure the commonalities of a demographic phenomenon that occurred almost simultaneously across Eurasia. Prenatal sex selection from Albania to Korea does in fact follow similar mechanisms with almost identical root causes. Sex selection is simply a recent adaptive behavior by couples to avoid births of the unwanted sex and it corresponds to a rational strategy in response to a set of changing constraints and opportunities. To understand its logic, we need to distinguish its three indispensable preconditions: the perceived benefits of sex selection guided by gender preference, the availability of means to implement it, and the additional urgency imposed by reduced family size (Guilmoto, 2009). I examine these three factors separately (**Figure 1**).

Son Preference

Son preference constitutes the primary factor behind prenatal and postnatal discrimination and it plays the role of the 'demand factor' in our equation: births of girls are avoided because of a skewed gender valuation system in which boys get preeminence. When given a choice about abortion, food sharing or health expenses, some families tend automatically to favor boys. In most cases, this is because they want to ensure the birth of at least one boy. Put differently, what parents want to expressly avoid is a family with no son. The cultural and political contexts may widely differ, but the pressing need for a male progeny is the common trait from the Balkans to East Asia (John et al., 2008; Murphy et al., 2011; Kaser, 2008). Here are a few illustrations in the way this preference for sons plays out in different settings.

Girl children may first be seen as more 'expensive' to bring up, mostly for security or honor-related reasons. When older, young women are also seen as more difficult to marry off, and this is particularly true in South Asia when marriage payments come essentially from the bride's family. But the low valuation of women becomes more obvious after marriage and sex-selecting countries inevitably correspond to areas where married women leave their natal family to join their husband's. As a result, bringing up and educating women are perceived ultimately as a loss and equivalent to 'watering the neighbor's garden' since all the parents' efforts will benefit another family. This feeling is due to the fact that newlywed women will become an active member of their husband's family in kinship systems characterized by strong virilocality or patrilocality. In patrilineal societies, married sons stay close to their parents and often coreside with them. They often share residence, agricultural land, or business interests with their parents. They contribute to most aspects of their parents' well-being in terms of physical protection, affection, economic support, and material assistance. In societies with limited individual instruments of social security (health insurance or pension benefits), family solidarity is a key to old age support and to withstand unanticipated health or economic shocks. Without a son, parents would be clearly at risk especially since customs sharply disapprove of being supported by one's married daughters. In patrilineal societies, solidarity and living arrangements within the family are strictly asymmetrical and exclude married daughters that belong to another family by virtue of marriage.

Support to the patrilocal family receives a very strong social sanction in the form of 'filial piety', held as a prime virtue in many Asian countries. But this lifelong support exerted strictly along the male line also has implications beyond the life of parents since many religious or traditional systems of belief also require male progeny after their death. Sons may be indispensable in funerary rituals or ancestors' worship, so that the need for sons has an indefinite horizon. To these immaterial benefits of male children, we should also add the status and honor symbol of fathering sons and perpetuating the family name. Couples with no son are lambasted and discriminated against for failing to prolong the patrilineal lineage, with effects ranging from constant sneering to inferior status for men and from domestic violence to repudiation for women. Similarly, the birth of sons is celebrated with great fanfare when that of girls is often a source of lament (Croll, 2000).

This entrenched preference for sons is often seen as an effect of wider gender inequity. It should not, for son preference is often unrelated to many other manifestations of gender discrimination at work, in the family, workplace, or public spaces. Women in China and Vietnam have for instance reached a high level of social and economic autonomy, but with apparently little effect on traditional bias against girl children. Conversely, we can see no prenatal sex selection in many countries where women are otherwise discriminated against by law and officially barred from access to the same economic, legal, or political position as men. When investigated further, son preference and the gender hierarchy it epitomizes appear closely linked to the nature of kinship systems that determine particular marriage, inheritance, and coresidence customs. All observations made earlier on the factors behind son preference presuppose a strictly patrilineal and patrilocal family organization. In more bilateral societies, when

Figure 1 The three preconditions for prenatal sex selection.

the mother's and father's family are on a somewhat equal footing, discrimination against girls simply does not make sense. This can be illustrated by the absence of sex selection in countries close to China, India, and Vietnam such as Sri Lanka, Thailand, or Indonesia. Kinship rules hold a larger sway than religious or ethnic affiliation when it comes to gender preference and they are strictly enforced to ensure the reproduction of family systems (Chakraborty and Kim, 2010).

Technology and Fertility Decline

In addition to gender bias, there are two other indispensable factors for sex selection to occur (Guilmoto, 2012b). The next precondition is a typical 'supply factor' related to the availability of effective techniques to avoid female births. Sex selection has been made possible at this scale only because of a recent technological breakthrough. Of course, methods for influencing the birth of a son have long existed in son-preferring societies. In India, pilgrimages to temples and other specific rituals are for instance thought of as a way to improve the chance of having boys. Prescriptions related to the timing of the intercourse and to the diet of pregnant women are also supposed to affect birth masculinity in many settings. But these prenatal 'folk methods' were probably of limited effectiveness. Postnatal methods of sex selection were also common, starting with female infanticide, a most radical method long attested in parts of South and East Asia. Selective infanticide was often linked by hypergamic norms among higher-status groups, but at times it simply represented a crude way to avoid a redundant female birth. A more common way to eliminate female children is through neglect after birth. Higher mortality rates are the undeniable outcome of discriminatory attitudes toward daughters that translate into passive discrimination. Yet, all these techniques are mostly remnants for the "ancien régime" of sex selection. In fact, they were all rather ineffective, low-tech methods, with the exception of infanticide, which for its part entailed huge psychological costs.

The first change took place when modern contraception became available, allowing women to stop childbearing once they had reached the desired gender composition. As a result, many families end with a boy as the last child as is observed in Vietnam or India. This strategy is definitely biased toward boys, but it has no impact whatsoever on the overall sex ratio of births that remains only determined by random biological factors. The contraception revolution also pointed to a new trend, the desire to control family size and the new possibility to actively avoid unwanted pregnancies. At about the same time, the new prenatal diagnostic techniques developed in industrialized countries started to spread in richer Asian countries during the 1980s, making sex detectable after 3 months of pregnancy. After 1980, many clinics in Asia were already offering sex diagnosis services. When this technology hit countries like India, women immediately understood that sex detection could allow them to opt for sex-selective abortion of female fetuses when they only needed a son (Ramanamma and Bambawale, 1980). Combined with abortion, prenatal sex diagnosis provided a unique tool to implement a more systematic form of sex selection (Miller, 2001).

In the former socialist world, from Eastern Europe to Vietnam, access to modern technology emerged only with the introduction of the new private health care facilities that proved more flexible to respond to the emerging demand for sex selection. In some other countries, the main issue remains access to abortion, which may be strictly outlawed or limited to lifesaving situations. Ultrasonography has gradually become both relatively easy to implement and inexpensive after a rapid fall in the price of scanning machines. More recently, new methods have emerged. Some allow the early detection of the sex of the fetus, using blood of women during the second month of pregnancy. Other high-tech techniques are linked to *in vitro* fertilization or preimplantation genetic diagnosis. These techniques are getting common in industrialized countries, but remain often inaccessible in Asia. Yet, what these new developments suggest is that future advances in reproductive technologies will inevitably make prenatal sex selection easier and that abortion may soon be outdated as a method to avoid unwanted girls (Dondorp et al., 2013).

Fertility level is the last of the three preconditions of this analytical framework and is the easiest to understand. It stems from the impact of fertility decline on the gender composition of the family. With six children, the odds that parents get six daughters and remain without a son are indeed very low (1.4%). But with two children, the risk becomes much higher (about 24%). In other words, parents who wanted a son in the past were most likely to have one after successive births. But as fertility declines, the probability of parents remaining sonless increases. At the same time, women in need of a son are also less ready to undergo repeated pregnancies and to have unwanted daughters. Increasingly risk-adverse and economically conscious parents refuse to submit themselves to a biological roulette and are now in a position to decide both the quality and the quantity of children they will have.

In addition to these social and economic considerations, family planning regulations introduced in several countries such as China and Vietnam have increased the 'marginal cost' of an additional child through various fines and penalties. Some have projected that fertility control in China was the main cause for sex selection. Yet, the skewed sex ratio also observed among other Chinese populations in Taiwan or in North America suggests that family planning was only one factor behind skewed sex ratios.

The Implications of Sex Selection

Gender discrimination plays out in two sequences. The first one is the immediate disappearance of girls at birth (or during early childhood) while the second one refers to future demographic disturbances among adults. The routine elimination of girls before their birth is no doubt the most extreme symptom of women's contemporary undervaluation that goes well beyond all other forms of discrimination. Since Amartya Sen's pioneer paper on missing women (Sen, 1990), we can measure the extent of the resulting gap across populations. Within families, the imbalance is mostly invisible since parents who abort female fetuses often have had prior girls. But when compared across larger communities, figures point inescapably to a surplus of boys. It is in fact possible to get a better idea of the actual rift between male and female by using demographic estimates on the age and sex distribution

for entire populations. 'Missing women' are women that ought to be found in population censuses if the sex distribution was not skewed toward men. By applying sex ratios by age computed for nondiscriminating countries, from Latin America to Europe, and correcting for age and mortality variations, it is possible to assess the number of women that are apparently missing from demographic records in Asia and Eastern Europe.

Using such a technique in conjunction with the United Nations Population Division population estimates, we obtain a total gender gap of 117 million women missing in 2010 (Table 2). Most of them should be found in China (66 million) and India (43 million). This large figure reflects in part the recent rise in sex-selective abortions, but also the cumulated toll of excess female mortality in the past. It is equivalent to the female population of Brazil or Indonesia, respectively the fifth and fourth most populous countries in the world. It represents about 8% of the female population in affected countries.

Among these missing women, we find 39 million of them would be below 20 years of age. This corresponds to the cohorts born since 1990, covering roughly the period when prenatal sex determination started to spread outside industrialized countries. The proportion of missing girls is especially high in China where they account for 14% of the women below 20 years of age. In India as a whole, where prenatal sex selection is less frequent, 13 million girls can be estimated as missing, but the contribution of excess mortality to this gap is also significant in India. China and India taken together account for 95% of the gender gap among the youth. The gender gap remains close to or above 5% in the Republic of Korea and in East-European countries.

A second way to look at sex imbalances at birth consists in examining their longtime consequences. This analysis starts with a set of demographic projections, in which the SRB is adjusted according to different future scenarios. These demographic simulations provide a precise description of future distortions in the age and sex structures of affected countries such as China and India. Of primary interest is the ripple effect of current sex imbalances at birth onto the young adult population after two or three decades. Projections show that even in the optimistic scenario of a rapid return of birth masculinity back to normalcy, men in China and India are bound face a serious 'marriage squeeze' in the years to come. Men will vastly outnumber women of marriageable age and saturate the marriage market for several decades, with a 60% surplus of prospective grooms over potential brides. Demographers have worked different adaptive scenarios whereby men would defer marriage by several years, but the magnitude and duration of birth imbalances preclude any demographic adjustment (Guilmoto, 2012a). The size of this 'male surplus' will be clearly too big to be offset by international migrations of potential brides or grooms. Moreover, trends observed elsewhere in East Asia or Western Europe suggest that women are likely to marry older and in smaller proportions in the future, a change bound to exacerbate the squeeze effect of their demographic deficit on the marriage market. Consequently, not only will a lot of men have to marry much later than in the past, but a rising proportion among them will also not be able to find a wife at all. The necessary readjustment of marriage systems will happen in patrilineal countries where family reproduction precisely depends on the male line and where only a small proportion of men remained unmarried in the past. Compared to Western societies where both male and female singlehood have long existed and where same-sex unions are gradually legalized, marriage systems in patriarchal societies are rather inflexible and allow limited leeway in case of a significant male surplus in the marriage market.

This unheard of situation has given rise to many speculations about its upcoming repercussions, ranging from rising male homosexuality and HIV AIDS contamination to human trafficking and international conflicts (Hudson and den Boer, 2004). But research recently conducted in some of the most vulnerable areas of China and India confirms the mounting pressure in women-scarce rural areas with significant social, sanitary, and demographic consequences on affected communities (Kaur, 2013; Li et al., 2010). Men resort to bride import from other, poorer regions when they can, and have at times to rely on existing criminal organizations for that purpose. An even higher proportion of men from underprivileged backgrounds seem condemned to involuntary celibacy, with married life becoming a new unattainable status because of their economic or social situation. In fact, if sex selection has mostly affected girls of higher status – since prenatal gender bias is more common among the rich – the price will be later paid mostly by men from the poorest strata. Sex selection is often considered a typical environmental Tragedy of the Commons in which opportunistic behavior by rational individuals leads later to the depletion of the resources and to a collective catastrophe. But a closer gender and class analysis suggests that the dividends and retributions stemming from the manipulation of biology will not be equally and simultaneously shared across society.

Table 2 Gender gap (missing women) by country in 2010

	Number of missing women			
	All women		*Women below 20 years*	
	In thousands	*%*	*In thousands*	*%*
Afghanistan	1097	7.2	502	5.7
Albania	40[a]	2.5	15	3.1
Armenia	31[a]		31	7.4
Azerbaijan	104		104	7.8
Bangladesh	2020	2.8	354	1.2
China	66 163	10.3	23 687	14.2
Hong Kong	27[a]		27	4.4
Georgia	19[a]		19	3.8
India	43 267	7.3	13 197	5.6
Montenegro	2[a]		2	2.7
Nepal	114[a]		114	1.7
Pakistan	2907	3.4	281	0.7
Singapore	114	4.5	11	1.9
South Korea	533	2.2	260	4.8
Vietnam	245[a]		245	1.7
Total	116 685	7.7	38 850	7.6

Numbers given in thousands.
Percentages computed over the corresponding female population.

Future Directions in SRBs

No one believes though that current sex imbalances at birth reflect a new demographic equilibrium and that they will persist indefinitely. Skewed sex ratios appear socially unsustainable in the long run. But this analysis suggests that prenatal sex selection depends on the conjunction of three preconditions and some are unlikely to improve in the near future Access to sex selection technology will continue to expand, even if some countries have actively attempted to ban prenatal sex diagnosis. Techniques to influence the sex of the births will continue to improve and spread across the world, making sex selection easier to implement than today. With countries offering state-of-the-art preimplantation technologies such as the United States or Taiwan, we may even expect the development of a new form of sex selection tourism. In a similar fashion, there is no reason to expect any significant turnaround in the low fertility situation that initially encouraged parents to plan the sex composition of their family. Even where stricter family planning regulations are relaxed in East Asia, low and ultralow fertility will largely remain and prevent parents from having more children in the quest for a son.

A reduction in son preference is therefore the only factor likely to bring about a lasting change. The bias against girls seems to have hardly changed over the last decades in view of persistent high sex ratios, but there are signs of a downturn. South Korea's experience in sex selection shows that the preference for boys over girls can recede and bring the sex ratio down to a normal level. In this country, patriarchal kinship institutions inherited from Confucian traditions have given way to less asymmetrical family structures in which daughters play a greater role. This evolution has been mostly attributed to the effect of social and economic change and to the new educational and employment opportunities offered to women by the rapid development that took place since the 1970s (Chung and Dasgupta, 2007). The prohibition of sex selection was also introduced and enforced right from the 1980s. In fact, the policies recently set up by many governments in other countries to enforce gender equity in social relationships and in family laws and sensitization campaigns can only accelerate this transition away from entrenched male bias. Apart from South Korea, there are now discernible indications of decline in birth masculinity levels in several parts of India and China, which suggests that the downturn, however slow, is probably already underway. The overall picture remains complex since in spite of a potential decline in the two largest world populations, prenatal sex selection might still spread in the future to new countries in Africa or in the Middle East when fertility declines and access to prenatal reproductive technologies progresses.

Mission: Proselytization and Conversion

Abstract

This article concentrates on the concept and practice of mission within the Christian tradition, and on interpretations of missionary activity by historians, social scientists, and theologians. Attention is paid to the origins of the terminology of Christian missions in the Jesuit order in the sixteenth century and to the more recent history of 'mission' as a theological concept within the churches. Developments in historical and anthropological scholarship in this field include the shift from earlier approaches which stressed the material connections of missions with the colonial powers toward a concern with elucidating the complex patterns of religious and cultural exchange created by missionary encounters. These trends are related to recent scholarship in African, South Asian, Chinese, and Latin American studies. Mention is also made of the growing interest by sociologists and feminist historians in the significance of missionary organizations for the sending and receiving cultures in modelling both conservative and innovative patterns of gender relations. The article concludes by noting attempts by many Christian theologians to dissociate the concept of mission from proselytization.

Mission: Proselytization and Conversion

The concept of a universal mission to the world is embedded in different ways in the monotheistic religious traditions of Judaism, Christianity, and Islam. Judaism, though its scriptures contain strong elements of universalism, has in modern times ceased to be a missionary religion. Islam, by contrast, continues to win converts in large numbers, in part because of the appeal to peoples threatened by modernization of the Muslim concept of the immutability of the Shari'a or divine law. In this article 'mission' refers primarily to the activity of the churches in commending the doctrinal beliefs and moral values of Christianity as worthy of universal acceptance. 'Proselytization' (or proselytism) derives from the Greek *proselytos* – the term used by the Septuagint (the Greek version of the Old Testament) to describe a non-Jew who adopted the Israelite faith in Yahweh – and has come to mean the recruitment of converts from other religious systems and communities. Proselytization traditionally has been regarded as central to Christian mission, but does not necessarily constitute its totality. Medical and relief work, Christian education, the promotion of agricultural development, and agitation for a just international economic order, are now seen by Christians as integral parts of the mission to bring the world into conformity with Christian values. This article surveys the history of the term 'mission' and the missionary activities of the churches since the eighteenth century, reviews recent scholarship on the missionary movement and conversion, and notes attempts by many theologians to dissociate the concept of mission from proselytization.

The History of 'Mission' and 'Missions'

The Terms 'Mission' and 'Missions'

The use of the Latin term *missio* to describe the sending of Christians to propagate the faith among unbelievers was pioneered by Ignatius Loyola in the sixteenth century. Senior members of the Jesuit order vowed to go wherever the Pope might send them, to 'missions' among either the Catholic faithful or infidels, to promote the glory of God and the good of souls (Ross 1994). The widespread application of the singular vernacular term 'mission' to the overall activity of the church in the world is, however, more recent, dating only from the 1950s, when both political challenges and theological questioning compelled missionary theorists to re-evaluate precisely what it was that God had supposedly sent the church into the world to do. Until then, the plural term 'missions' was much more common, denoting the range of agencies deployed by both Catholic and Protestant churches to pursue the agreed aim of converting non-Christians. That usage remains widespread among American Christians and also among historians and social scientists concerned to investigate Christian missions simply as a human phenomenon.

The Modern Missionary Movement

Christian missions up to the mid-eighteenth century were conducted chiefly by the Roman Catholic and Russian Orthodox churches (the latter mainly in Siberia). The Roman Catholic missionary endeavor lost impetus following the suppression of the Jesuit order by the papacy in 1773, and the initiative passed to Protestants influenced by German pietism and the ensuing movements of evangelical revival which spread from central Europe to North America and Britain. The Protestant awakening culminated in the formation of numerous voluntary societies, beginning with the Baptist Missionary Society (1792) in Britain, the American Board of Commissioners for Foreign Missions (1810) in America, and the Basel Mission (1815) in continental Europe. For much of the nineteenth century these societies experienced only limited success in terms of both domestic recruitment and conversions overseas. From the late 1870s this picture changed as missionary enthusiasm converged with forms of

popular imperialism, and as indigenous peoples became increasingly attracted by the literacy and access to literature (both vernacular and English) which the missions offered. By this time, European Roman Catholic missions had also revived, stimulated by the recovery of the papacy and the formation of new religious orders, such as the White Fathers, founded by Cardinal Lavigerie in 1868. Competition between Protestant and Catholic missions was frequently intense, and often coincided with imperial rivalries. North America was regarded by the Catholic Church as technically a mission field until 1908, and the first American Catholic missionary order, the Maryknoll Fathers and Brothers, was not founded until 1911.

By 1910 Protestant foreign missionaries working in Africa, Asia, and the Pacific numbered some 19 000, of whom 71% were male or female lay persons. Catholic missionary numbers were almost certainly larger. In both Protestant and Catholic missions, however, the bulk of the work of evangelization was performed by indigenous (and primarily lay) Christians. After the First World War, the Americans supplanted the British as the predominant force in Protestant missions, though the older denominational boards progressively were eclipsed by newer interdenominational missions of evangelical or fundamentalist inclination (Hutchison 1987). Since the 1960s, many western mission agencies have dwindled in size, but their place has been taken by new missions from the nonwestern world, notably from Korea. By 2000, the total Christian foreign missionary force had risen to an estimated 420 000.

Recent Scholarship on Christian Missions

The Historiography of Missions

Until the late 1960s most writing on Christian missions tended to be confessional, often hagiographical, rather than scholarly. This was despite the fact that missionaries had made substantial contributions to the development of secular disciplines such as linguistics, Sanskritic and oriental studies, and anthropology (Walls 1996). Since the 1960s historical and anthropological scholarship on the missionary movement has proliferated, prompted by heightened awareness of the importance of religion in colonial encounters and the shaping of indigenous nationalist movements. Some of the pioneering African historiography of the 1960s identified a growth in racist and colonialist attitudes among late Victorian missionaries as crucial in the origins of West African nationalism (e.g., Ajayi 1965). The anticolonial reaction of the 1960s and 1970s encouraged writing by historians, anthropologists, and theologians that interpreted the missionary movement as the ideological expression of western colonialism. Such interpretations were able to point to the close connections between missions and western imperial expansion in contexts such as China, and to the consistent use by missions of terminology which branded nonwestern peoples as benighted heathens who needed 'civilizing' by the supposedly Christian west.

Since the early 1980s a strengthening reaction to, or at least modification of this tradition, has been evident. Scholars from a variety of disciplines (including, notably, literary studies) have become increasingly dissatisfied with models which erect a simple dichotomy between 'colonialist' missions and the 'victims' of colonialism (see *Religion: Culture Contact*). As the focus of imperial historiography has shifted from the materialist preoccupations of an earlier generation of Marxist-influenced historiography to a characteristically postmodern concern with the power of narrative and the construction of mentality and identity, scholarship has become less interested in the formal connections of missions to the apparatus of colonial rule and more concerned to elucidate the complex patterns of religious and cultural exchange created by missionary encounters (Peterson and Allman 1999). Rather than regarding indigenous converts simply as passive dupes of colonial pressure, scholars now are inclined to delineate a range of indigenous responses varying from outright rejection to transformative appropriations of the Christian message and the biblical text. This emphasis accords with the primacy of indigenous agents in transmitting the message, and with the fact that the rate of conversion to Christianity in the nonwestern world has accelerated, not slackened, since decolonization. Particular attention has been devoted to the cultural significance of vernacular translation, which committed missionaries, whether consciously or not, to a 'radical pluralism' wherein 'all languages and cultures are, in principle, equal in expressing the word of God' (Sanneh 1989, Walls 1996). The development of a vernacular literature, and especially a popular religious literature, to which mission Christianity contributed so fundamentally in nonwestern contexts, has been identified as the essential precondition for the transmutation of an ethnicity into a nation (Hastings 1997). The current academic trend does not, however, necessarily imply a more favorable estimation of the missionary impact. Perhaps its most influential exponents, the American anthropologists Jean and John Comaroff, despite an emphasis on the complexity and two-sided nature of missionary encounters in nineteenth-century southern Africa, continue to depict missionaries as 'colonial evangelists,' for whom language was not a medium of cultural liberation but rather a field of discourse whose terms they dominated in order to achieve 'the colonization of consciousness' (Comaroff and Comaroff 1991, 1997).

Regional Studies

The shift in focus toward the dynamics of conversion has been most marked in African studies, perhaps because of the remarkable growth of Christianity in sub-Saharan Africa (from some 60 million adherents in the 1960s to as many as 300 million by 2000). There are signs, however, of a similar trend in South Asian studies. The literary scholar, Gauri Viswanathan, though an adherent of Edward Said's school of 'Orientalism,' has argued that in British India, conversion to mission Christianity was a profoundly destabilizing influence, disrupting the stable categories of religion and nationhood on which the Raj depended, and compelling a professedly secular colonial administration to grapple with fundamental issues of civil rights (Viswanathan 1998). Studies of conversion by tribal and untouchable (or Dalit) peoples in India have followed precedents set by Africanist scholarship in interpreting conversion to Christianity as

a process, usually collective, which frequently offered those involved a more satisfactory framework of cosmological meaning and a more advantageous communal identity than the obvious alternative of adherence to Brahmanical versions of Hinduism. Frykenberg (in Hastings 1999) has observed that 'no mass movement of conversions in India was ever led by a European.'

Scholarship on conversion to Christianity in China, where the material linkages between missions, converts, and the protection of the imperial powers were more blatant than anywhere else, has been relatively slow to follow the trend set by the Africanists and South Asianists. Interpretations of Christianity in China during the missionary era have tended until recently to concentrate either on mission ideologies and strategies or on hostile antiforeign reactions to missions, rather than on the motivations of those Chinese who did convert (but for a recent collection which pioneers a more indigenous perspective on the Christian history of China see Bays 1996). The substantial growth of popular Christianity in Communist China since the era of the Cultural Revolution (1966–79) necessarily remains largely uncharted territory for scholarship.

Scholarly analysis of the impact of Christian missions on Latin America for long concentrated on the close connections between the Catholic Church and Iberian expansion which followed Columbus's 'discovery' of America in 1492 and the papal bull of 1493 which in effect divided ecclesiastical control of the continent between the Spanish and Portuguese crowns. More recently, attention has been turned to the phenomenal growth of popular Protestantism (especially Pentecostalism) in Latin America since the 1950s (see Christianity: Evangelical, Revivalist, and Pentecostal). The primary question currently being debated is parallel to that posed by writing on African Christianity during the colonial period: to what extent can the current success of Protestant proselytism in this most traditionally Catholic of continents be interpreted satisfactorily as a function of North American cultural and political influence, or should greater emphasis in fact be placed on the ability of Pentecostalism to meet the felt needs of the Latin American poor? (Hastings 1999, Martin 1990).

Sociological and Gender Studies

Within the social sciences, interest in missions has been for obvious reasons more pronounced among anthropologists than among sociologists. Very few sociologists have devoted attention to the unusual nature of mission organizations as typically voluntary bodies which have needed to maintain control at a formidable distance over highly motivated and frequently eccentric individuals, and at the same time satisfy the expectations of their supporting domestic constituencies. One such study of how religious zeal was both exploited and contained through institutional mechanisms examines the Basel Mission on the Gold Coast (now Ghana) in the nineteenth century (Miller 1994).

Much of the recent writing on missions within the social sciences examines the significance of the missionary movement from a feminist perspective. For most of the nineteenth century, Protestant missions were overwhelmingly male institutions. Most societies did not accept single women candidates, and missionary wives were not counted as missionaries in their own right, despite making in many cases major contributions to the work of the mission. The first Protestant missionary society specifically for women (the Female Education Society) dates from 1834. The first such societies were often inspired by the needs of the high-caste women of the Indian zenanas, who, being secluded from public contact with men, could be reached and educated only by women. From the late 1860s, female or zenana missionary societies became common on both sides of the Atlantic, either as autonomous institutions, or as female auxiliaries to existing denominational societies. These bodies enabled women to fulfil public roles both in their homelands and overseas which had few parallels in other contexts. From the 1870s, the denominational societies themselves began to accept single women candidates. They did so to varying extents, but the trend was accentuated by the readiness of many of the new nondenominational 'faith missions' to recruit single women (Robert 1996). By 1910 the missionary movement had become a predominantly female enterprise still controlled by men. Whilst still influenced by male assumptions about the proper restriction of women to the domestic sphere, it modeled a different reality. In that year, single women made up nearly 28% of the entire Protestant missionary force, and married women a further 28%. It seems likely that a similar gender distribution obtained for most of the twentieth century. The proliferation of missionary sisterhoods, first in France in the late nineteenth century, and then more widely, produced an even greater predominance of women in the Catholic missionary movement. Missionary women have thus become a major concern of scholars investigating what has been termed 'imperial feminism,' which is held to have combined 'colonial' views of racial difference with stances that were in practice subversive of traditional concepts of gender difference (Chaudhuri and Strobel 1992).

Mission and Proselytism in Theological Discourse

Whilst secular scholarship on missions has tended to move away from approaches which interpreted the proselytizing imperative as inescapably connected with the colonial system of material domination toward indigenous perspectives which emphasize the volitional agency of the convert or convert community, much Christian theology since the 1960s ironically has continued to regard coercion as intrinsic to the concept of proselytization, and has therefore been anxious to divorce 'mission' entirely from proselytism. One animating impulse of this concern has been the experience of the Roman Catholic, Orthodox, and other ancient eastern churches in finding their faithful to be the objects of often aggressive and well-funded evangelism by Protestant groups, particularly from the USA. A report jointly produced by the Roman Catholic Church and the World Council of Churches in 1970 sought to distinguish Christian witness from proselytism, defining the latter as 'improper' attitudes or behavior which employed coercion and thus violated the rights of the human person. Such a distinction has proved an unstable one, since almost any act of religious witness can be interpreted by the

recipient as being coercive or invasive. Since the collapse of Communist regimes in eastern Europe in 1989 and the dissolution of the Soviet Union, opposition to proselytism from the west has motivated legislation designed to curb the missionary work of those regarded by the Orthodox churches as 'sects.' More broadly, from the perspective of a Muslim, Hindu, Buddhist, or Jew, all Christian missionary activity is proselytizing in intention and effect, leading inevitably to the severance of the convert from community and even nation. Some Christian theologians accordingly have taken their opposition to proselytism toward its logical conclusion by denying that the conversion of adherents of other religions is a valid missionary objective for Christians. It then becomes difficult to resist the application of the same principle to the conversion of humanists or adherents of any belief system whatever, and the universalism intrinsic to the Christian theological tradition becomes unsustainable. Religious pluralism is no new phenomenon, but all religious believers in the western world now face unprecedented social and cultural pressures to accept the permanence and ideological absoluteness of pluralism. In the younger churches of the nonwestern world, whose role in world Christianity is becoming increasingly dominant, insistence on the inescapable connection between mission and proselytization remains strong. It may therefore be predicted that the twenty-first century is likely to see an even more heated debate within the churches about the validity and meaning of mission, proselytization, and conversion.

Abstract

Mixed methods research is an eclectic, pragmatic approach to employing combinations of research tools in answering multifaceted questions by seeking multiple, multilayered answers. It has gained in popularity since the 1980s as a third option to the either-or dichotomy (either quantitative or qualitative research) that had previously dominated the social and behavioral sciences. This article first presents three contrasting sets of beliefs that have characterized mixed methods in the contemporary literature. The article then discusses several issues in mixed methods: research questions (the dominance thereof), research designs (four families), data collection/analysis strategies (qualitative and quantitative), and postanalysis integration.

The field of mixed methodology (and social research methodology, in general) has changed so much in the past two decades that it looks chaotic at times. (We view *mixed methodology* as broader and different from *mixed methods (MM)* or *mixed methods research (MMR)*. The former is a set of concepts, rules, methods, norms, and expectations, including research ethics. The latter is the practice or concrete product of mixed methodology.) A quick look at how it is conceptualized within and across disciplines would easily reveal the immense diversity of worldviews, designs, data collection and analysis, permissible inferences, quality audits, and utilization approaches. Undoubtedly, a degree of diversity is a healthy indicator of a growing and lively community of scholars who utilize a methodological approach. On the other hand, without systematic attempts to create bridges (higher-order frameworks) between diverse conceptualizations and create a common language to facilitate communication within such a highly diverse community, a sense of (at least temporary) chaos is inevitable.

Mixed methodology was received well in 1980s as a reaction to dichotomizing research methodology, separating both the scholars and their approach to inquiry into two somewhat amorphous qualitative (QUAL) and quantitative (QUAN) categories and communities. The qualitative research community emerged and was clearly defined as a reaction to the dominant status quo in social science disciplines in which research was heavily centered on hypothesis testing, promise of objective answers to important social questions, and belief in isolating and finding clearly delineated causes for outcomes and effects. Qualitative research emerged as a community with a promise of searching for multiple explanations, from multiple perspectives, within sociopolitical contexts of occurrences. Cohorts of graduate students were caught in an either-or dilemma of selecting either quantitative or qualitative research, but not both. Journals oftentimes sent a similar message. Change is rarely smooth and without resistance. In the past two decades, there has been a clear 'us' and 'them' designation in many writings and references within both of the two broad communities of scholars.

The mixed methods 'movement' (as we and others have called it) was a reaction to the dichotomy. Rejection of the dominant dichotomy resulted in the possibility, desirability, and plausibility of conceptualizing mixed methods. This is seen in three somewhat different clusters of beliefs where (1) mixed methods is seen as a point on a multidimensional continuum with QUAL and QUAN orientations or packages of beliefs at the poles (QUAL———QUAL/quan———QUAL/QUAN———QUAN/qual———QUAN); (2) mixed methods is conceptualized as an interactive bridge between the qualitative and quantitative orientations (QUAL←→QUAN); and (3) mixed methods is considered either irrelevant or as an all encompassing orientation that considers the popular dichotomy (of QUAL and QUAN approaches) both false and irrelevant. Below, we consider each of these sets of 'beliefs' about mixed methodology (i.e., mental models or sets of cognitive 'statements' linking mixed methodology with valued attributes). Each of these mutually noninclusive sets has explicit or implicit advocates.

The first set of beliefs (the multidimensional 'continuum orientation') is held by those who consider each research project as an attempt to answer a research question or a set of interrelated research questions via *the* combination of QUAL and QUAN perspectives and methods appropriate to the questions (Johnson and Onwuegbuzie, 2004; Teddlie and Tashakkori, 2009). Virtually every research project, according to this type of conceptualization, inherently needs to include a combination of the two approaches in some degree or another. This belief system includes the differentiation of designs according to which approach is 'dominant' or takes the biggest intellectual space in the research project (i.e., leading to a notation system to classify designs in QUAL–quan, QUAN–qual, and similar forms). (Using notation from Morse (1991), QUAL–quan signifies a study in which qualitative research is core and quantitative research is subsidiary, and QUAN–qual signifies a study in which quantitative research is core and qualitative research is subsidiary. In both cases, it is important that the subsidiary approach provides an added value to the overall research study.)

According to the second set of beliefs, conceptualizing mixed methods as an interactive bridge between two distinct approaches (qualitative and quantitative research) involves

explicitly recognizing two identifiable and distinct sets of methods/approaches, each with its own community of scholars. These mixed methods projects employ the two sets of methods/approaches side by side (coexisting) or in a dialectic manner (Greene, 2007). Scholars in this community have tried to find common or symbiotic grounds between the two sets, both in terms of ideas and methods, in order to make it possible for the two communities of QUAL and QUAN researchers to understand each other, and, more specifically, so that both QUAL and QUAN can be used interactively in single research studies to add explanation and understanding to important research questions. Mixed methods research designs are conceptualized with the first and second belief sets in two or more parallel or sequential components or strands, with each strand (i.e., a combination of conceptualization, methodological, analytical, and inferential stages) conducted separately within one of the two broad methodological grounds and linked at some level during and/or at the end of the process.

The third set of beliefs has strong roots in the early twentieth century history of social research in which there was no discernable differentiation between the two sets of methods or approaches to research. We call this the traditionalist age, as it was the time when traditional empirical research approaches were being formulated. This also was a time when disciplines were beginning to clearly distinguish themselves into departments in universities and department names were being decided upon. Multiple perspectives, questions with multiple components (that one can identify today as QUAL or QUAN), multiple complementary/competing methods of study, and integrated inferences were all employed by prominent researchers in social sciences in early- and mid-twentieth century (e.g., Festinger et al., 1956; Lewin et al., 1939; Sherif et al., 1961). In this traditional research community, the issue of the QUAL/QUAN dichotomy is irrelevant, either as two discrete categories or as poles of a continuum. Separation of methods and perspectives is not recognized as a necessary component of planning and implementing a research project, since it is not how research is done (in a way, the two poles are collapsed, with every research study being both QUAL and QUAN, at the same time, depending on the questions asked!) (see Brewer and Hunter, 2006; Waszack and Sines, 2003 for examples).

Consistent with the inherent 'return to roots' characteristic of this group, this subcommunity in MM might be called 'research traditionalists' whose dominant tenet is that the research question (not the paradigm) dictates all aspects of the research inquiry, leading to taking multiple perspectives and using whatever methods are necessary to find answers. The term 'aparadigmatic' also has been used by a few to describe this group of scholars (Greene, 2007). Pragmatism has emerged over time as a philosophical anchor for this rather large subset of the community of mixed methods scholars. According to this group, good research is just that: no discussion is needed about whether it is qualitative, quantitative, or mixed. In its current version, the 'Q labels' are seen as having had their moment but now as having outlived their usefulness (Onwuegbuzie and Leech, 2005).

Several scholars (e.g., Brewer and Hunter, 2006; Erzberger and Kelle, 2003; Hunter and Brewer, 2003) have identified mixed methods studies from the formative years of the traditional period. For example, Hunter and Brewer (2003) presented three such studies: (1) the Hawthorne studies, which began in 1924 and continued for several years (Roethlisberger and Dickson, 1939); (2) the studies of 'Yankee City' (Newburyport, Massachusetts) as an example of community life in the United States (Warner and Lunt, 1941); and (3) the Marienthal study which was conducted during the 1930s economic depression in Austria, but not published in the United States until 40 years later (Jahoda et al., 1971). In the Hawthorne studies (Roethlisberger and Dickson, 1939), the researchers used interviews and observations as they tried to understand what became known as the 'Hawthorne effect.' The Hawthorne studies lasted several years, were conducted by multiple researchers, and the overall research program emphasized experiments *and* extensive interviewing, observation, and life history data. Their work focused on the formal/structural side of an organization and especially the informal/human side of organizations.

At least in this point in time, most writings about mixed methodology, and most mixed methods research projects, seem to include a combination of the three sets of beliefs. We see all three sets of beliefs in our own thinking. Mixed methodology, broadly conceived, is often considered today as a 'third option' to research for many scholars. It is a highly eclectic and pragmatic approach to employing useful combinations of tools (i.e., methods) for answering multifaceted questions (i.e., formulated from different perspectives) and explicitly seeking multilayered and multiple answers. The biggest degree of divergence today is probably in conceptualizing the meaning of mixing. Meanings range from linking two clearly recognized perspectives/outcomes (QUAL and QUAN) while keeping each separate with its own assumptions and quality audit, to integrated methodology that incorporates multiple perspectives without explicitly differentiating or keeping the QUAL and QUAN separate.

We appreciate diversity and variation in perspective, but we generally consider it unfortunate when calls are made for formulating research questions *after* adopting/declaring a perspective, imposing strict and simplistic designs (e.g., selecting a 'design name' for one's project from a small set of preconceived names/designs), and so on. There are also lingering doubts about the human capabilities of a single researcher to examine problems via multiple lenses. A useful antidote to this last issue might be to use research teams, instead of requiring a researcher to do all of the hard thinking and work.

General Characteristics of Mixed Methods Projects

As mentioned above, despite a respectable divergence in what we called 'beliefs' about mixed methods, mixed methods researchers have many commonalities. For example, they often identify themselves as integrative and eclectic. Many work within a pragmatic worldview and encourage paradigm diversity and diversity of the research enterprise at all levels because of its potential to spur new growth and scientific understanding and advancement. They emphasize continua, balance, and a cyclical, iterative approach to research. They collect both narrative and numeric data, employ both structured and

emergent designs, analyze their data both via statistical and content/meaning analysis, and integrate the results in order to reach 'metainferences' that integrate qualitative and quantitative findings to provide better answers to research questions. They also acknowledge the unavoidable impact of their culture, worldview, and sociopolitical context on their purposes and questions for inquiry, eventually leading to selected methods and an inference process based on empirical results (Newman et al., 2003). There also is a widespread acknowledgment within the community that not all research questions require a mixed approach. For example, Johnson and Onwuegbuzie (2004) put it like this:

> In general we recommend contingency theory for research approach selection, which accepts that quantitative, qualitative, and mixed research are all superior under different circumstances and it is the researcher's task to examine the specific contingencies and make the decision about which research approach, or which combination of approaches, should be used in a specific study.

Research Questions in Mixed Methods Research

Research questions that call for mixed methods research are often multifaceted, having implicit or explicit interrelated components that might separately fit traditional qualitative or quantitative orientations. These combination questions often include both 'what and how' or 'what and why' of events, cognitions, and/or behaviors. Often, there is an overarching question that includes these general components, followed by a collection of separate qualitative- and quantitative-type subquestions. An example, from Tashakkori and Newman, 2010 is "What are the effects of teaching method X on achievement and self-perceptions of groups A and B?," with subquestions such as "Are groups A and B different in achievement and self-perceptions?," "What are the perceptions and constructions of participants in groups A and B regarding teaching method X and its impact?" and "How does teaching method X work differently in the two groups (if it indeed did)?"

Unique to mixed methods studies are questions regarding the nature of integration (i.e., how do the insight from multiple strands of the study, or the outcomes of data analysis in various strands contribute to an overall answer?). An example of such 'integration questions' might be "how do the two sets of answers contribute to a comprehensive understanding of the phenomenon under study?" Possible scenarios for answers to this question might be that the results complement each other (provide two alternative aspects/approaches to the phenomena), add to each other (more complete answers), or confirm/corroborate.

Mixed Methods Designs

Based on the planning/emergent process of research and types of questions, mixed methods designs can be conceptualized under three broad families of sequential, parallel, and conversion designs, leading to a fourth family (fully integrated) when combined (Tashakkori et al., 2013). Within each of these four design families, variation can occur on the basis of units of study (individuals, natural collections of units, or both), and the degree to which multiple strands (defined above) are planned versus emerge as the project is conducted (i.e., emergent vs preplanned questions and design) or both.

In sequential designs, later research questions can crystallize or other aspects of the study can emerge (such as Who needs to be sampled? What additional data need to be collected?) based on the findings from a previous strand. For example, participants in a randomized controlled/clinical trial who have not responded as expected might suggest questions and data sources for a next strand consisting of multiple case studies. In this example, the questions for the follow-up case study might emerge as a result of unexpected findings of the first strand, or they might have been developed in a preplanned manner (expecting lack of predicted response to intervention by at least some participants). Preplanned sequential designs predict certain outcomes (e.g., certain categories of responses, identification of certain subgroups based on the findings) would be necessary before the next phase of the study can be implemented.

Also in sequential mixed designs/studies, one might collect data in a separate/different sample of individuals for each strand, or select subsets of individuals from one strand to study in the next. The first case might also include selecting from two or more levels of a social system or organization, such as children to be tested in one strand, parents to be interviewed in another, in a multilevel mixed methods study. In short, in all these scenarios, the samples, procedures, instruments for data collection, or even data analysis techniques of a later strand are often dependent on the results obtained in a previous one.

Parallel mixed methods studies employ relatively independent strands of data collection and analysis, either simultaneously (concurrently), or with some time lag. The time frame for implementation does not change a parallel mixed project to a sequential one. The key differentiator of this group of designs from the previous (sequential) designs is that one strand is not dependent on the outcomes of another. Hence, the order and timing of implementation is flexible, partly depending on the practical logistics of the study. The findings and inferences emerging from multiple strands are integrated at some later point, after the data are collected and analyzed, in order to find a comprehensive answer to the initial multifaceted research questions. Different strands might use different samples at the same or multiple levels of a social system, or one strand might be limited to a subsample of the other one (e.g., a full sample is studied in one strand, while additional data are collected on a subsample in another concurrent strand).

In conversion mixed methods designs, the data (often narrative/qualitative) are analyzed both qualitatively and quantitatively, and inferences are made on the basis of both sets of analytic results. For example, themes are developed via content analysis of narrative data and then codes are assigned to these themes (or other aspects of narrative data) based on intensity of occurrence and the codes (as binary or categorical variables) are analyzed quantitatively (e.g., correlations, regression). In conversion designs, inferences are made on the basis of *both* sets of results (thematic analysis and statistical analysis) and the data and results are compared and contrasted or linked to each other. The data collected from an entire

sample might be analyzed via content and statistical methods separately. Alternatively, only the data from a subset might be converted and analyzed for subsequent strands.

Fully integrated designs incorporate a combination of the three basic types (parallel, sequential, conversion) in an interactive and dynamic manner. Variations in the sampling, data collection, and data analysis procedures that were just described above for the simpler families of designs are also applicable to this more dynamic and comprehensive family. For example, one might collect survey data in a large sample, then select two subsamples for the next step in order to collect observational data in one (second strand of the study), and then administer a personality test to another (third strand of the study), then analyze all the data in the three sets, then quantitize the observational data and statistically analyze it in a fourth conversion strand, and then finally link all four sets of outcomes together into metainferences. Two key points here are that (1) integration is integral to strong MMR and (2) MMR designs can be both creative and complex as we answer our research questions.

Data Collection and Analysis Strategies in Mixed Methods Research

Mixed methods researchers collect both qualitative/narrative and numerical data and/or convert one to another as an additional analytic strategy. The mixed data are collected either with a single method of data collection (e.g., questionnaires including both open- and closed-ended items), or using multiple methods of data collection (e.g., questionnaires and naturalistic observations at the workplace). The former is an example of *intramethod mixing* (i.e., using a mixed version of a single method of data collection) and the latter is an example of *intermethod mixing* (Johnson and Turner, 2003). Observations might be recorded by taking extensive notes to document as many of the interactions as possible, while also using highly structured protocols yielding numeric data. Sometimes, two types of data are collected sequentially in alternative intervals (e.g., 3 min of one, 3 min of the other, and so on). Similarly, one might conduct open-ended (qualitative, ethnographic) interviews that also have structured (closed-ended) items/components (i.e., intramethod mixing). Quantitative and qualitative approaches might be used in the same sample, or the more extensive data collection efforts might be limited to subsamples. Often, individual and/or focus group interviews start with broad questions and then increasingly focus on specific aspects or components of the phenomenon or behavior of interest. Data collection should always be tailored to the needs of one's research questions.

Depending on the nature of the data (e.g., narrative/visual vs numerical), appropriate analysis strategies are employed with each set. In sequential designs, each round of data collection and analysis appropriately and systematically follows the previous step. For example, if there is a plan/need to select specific types of units (e.g., effective schools, or better/worse than expected postsurgery recovery patients) for a study, the data collected in the previous strand must be analyzed accordingly (e.g., descriptive variable analysis and/or multiple regression to find regression residuals for selection of certain cases). In parallel mixed designs, the investigator might statistically compare experimental and control groups, while also, independently, conducting a thematic analysis of post-experimental interviews (or open observation notes if the individuals/groups were observed).

Postanalysis Integration

Being able to examine a phenomenon from multiple perspectives or vantage points (e.g., 'qualitative' and 'quantitative' perspectives or multiple stakeholder perspectives) is a definite advantage of mixed methods studies. There is a degree of comfort in finding consistency between the outcomes of such examinations, leading to greater confidence in the trustworthiness of the conclusions. However, consistency between the conclusions of multiple strands is not necessarily a goal and is not a requirement of a strong mixed methods inquiry. Integration of research results in mixed methods can also denote elaboration, complementarity, completeness, confirmation/disconfirmation, and so forth. Pending a thorough review of an 'inconsistency' to make sure it is not the result of data and/or analysis problems, the (inconsistent) outcomes can provide a broader and more complex understanding of the phenomenon under investigation by suggesting that (1) there are multiple aspects/dimensions of the same phenomenon, each abiding by a different set of rules/theories, (2) there is set of explanations that might provide the conditions for the applicability of the other, or (3) there are multiple plausible answers or stakeholder vantage points to the question.

The 'big picture' outcome of a mixed methods study depends highly on the degree of confidence in the conclusions/inferences made based on the findings of each stand, and their effective linking and integration. There are several frameworks for assessing the quality of mixed methods inferences. One approach to research quality suggests using separate evaluation criteria for the qualitative and quantitative components using the criteria associated with these components; this is seen in the 'multiple validities' type in Onwuegbuzie and Johnson (2006). *Multiple validities legitimation* ('validity' is viewed broadly) is the extent to which all of the pertinent validities (quantitative, qualitative, and mixed) are addressed and resolved successfully in a research study (Onwuegbuzie and Johnson, 2006). A 'cross-perspective' audit strategy also has been suggested (Tashakkori and Newman, 2010) in which qualitative standards/procedures (e.g., prolonged engagement, peer debriefing, triangulation, audit trail, negative case analysis, and others) are used to enhance the quality of inferences gleaned from quantitative findings, and the quantitative concepts (e.g., consistency between elements of the design, construct validity, investigator expectancy effects, and possible participant reactivity) are used for assessing the trustworthiness of the inferences based on qualitative findings. Another (and nonmutually exclusive) framework ('integrative framework,' O'Cathain, 2010; Teddlie and Tashakkori, 2009) provides an umbrella that includes the underlying logic of audits/strategies of both perspectives.

The umbrella (integrative) approach to assessing/maximizing the quality of inferences in mixed methods research studies has

focused on at least five components of strong inferences, and possible strategies to maximize each: (1) quality of research questions; (2) quality of research design components and their implementation; (3) quality of interpretation (of the findings); (4) quality of integration (of inferences from multiple strands of the study); and (5) quality of utilization, with specific attention to the value-added contributions of a mixed methods study to the quality of policy and practice, beyond simpler methodologies. Auditing and enhancing each of these five aspects of a mixed methods study incorporates known strategies from both QUAL and QUAN approaches, regardless of the type of data or findings. *Multiple validities legitimation* ('validity' is viewed broadly) is the extent to which all of the pertinent validities (quantitative, qualitative, and mixed) are addressed and resolved successfully in a research study (Onwuegbuzie and Johnson, 2006).

Given a reasonable degree of confidence in the quality of integrated inferences, transferability is the potential value-added contribution of the conclusions and recommendations for policy and practice. Transferability is broadly defined here as the degree of applicability or generalizability of conclusions of a mixed methods study to other individuals or entities (population transferability), other settings or situations (ecological transferability), other time periods (temporal transferability), other methods of observation/measurement (operational transferability), or in complex ways to subpopulations as seen in higher-level interaction effects (complexity transferability). Given the pragmatic nature of mixed methods studied, utilization quality is often evaluated in terms of transferability (contributions) to policy and practice. Practical theory (i.e., theory that works in particular places/contexts with particular people) is an ongoing goal of mixed methods research. Kurt Lewin (1951) expressed the spirit many years ago when he said "There is nothing so practical as a good theory" (p.169).

Conclusions

We started this article by discussing three sets of beliefs about mixed methodology (MM as a space on a multidimensional continuum of QUAL and QUAN approaches, as an interactive bridge between two separate and identifiable poles, or as an encompassing third option that does not consider the dichotomy as important for good research), with each leading to possibly different conceptualizations of mixed methodology. Regardless of an investigator's specific beliefs about mixed methodology, it is predominantly considered a pragmatic approach to problem solving, with the potential to provide a more diverse sets of tools than either of the two traditional approaches (i.e., QUAL and QUAN). Although not agreed by all, we contend that in mixed methods research, the research question, not the paradigm or purpose, should dictate the methods and strategies used in mixed inquiry. We are aware that some in the field advocate deciding on a paradigm or purpose for using integrated methodology (e.g., complementary, dialectical, transformative), rather than letting the research question drive the decision process. We wonder: Does it matter what the purpose of mixing was if the outcomes are clear and enlightening?

To us, the driving force behind planning a mixed methods study is the answer to an initial question: "Does the research question/problem beg for a mixed approach, instead of a simpler approach?" In varying degrees of contrast, there are suggestions (actually mandates!) by some others encouraging the investigators to first decide on why they value using a mixed approach (i.e., to have stronger inferences, to complement the findings of one with the other), then proceed to formulating research questions that fit within those values. Similarly, there are suggestions to declare a paradigm/worldview up front, then formulate one's research questions. Although we acknowledge the importance of being aware of one's worldview and/or purpose for a study, we consider them as parts of an investigator's engagement in the process of reflection about the research questions (i.e., reflective inquiry; Greene, 2007) and the entire study, throughout the entire project.

A lingering issue in mixed methodology is that of a priori decisions regarding 'dominance' of one approach or another in inquiries. This is largely consistent with the multidimensional continuum belief mentioned early in this article (e.g., QUAL + quan and QUAN + qual approaches). Although it might be useful to remain aware of where on the continuum of the combination of QUAL and QUAN a component falls, we do not have a priori any indication of its usefulness in terms of contributions to the quality of research inferences and the potential of transferability/utilization of the outcomes. It is not clear if/when such decisions are essential in planning of a project, or why/how doing so enhances the outcomes. We wonder: Does it matter which approach was dominant (or not), if the outcomes are useful for one's research questions?

Challenges and Opportunities in Mixed Methods Research

A challenge for mixed methods researchers is that they must learn specific methods, procedures, and techniques that have been traditionally identified as being qualitative or quantitative. They also must learn how to integrate understandings gleaned from these complementary or competing methods and approaches to reach metainferences (i.e., inferences or conclusions that build on or *integrate* quan and qual findings) that better inform researchers, professionals, and stakeholders. The challenges are substantial. The possible rewards are, however, even greater! Mixed methods research has the capability of providing understandings from multiple perspectives, deeper and wider than the two traditional approaches might be capable of providing. In many respects, mixed methods research uses the same strategies as everyday problem solvers, but in a more systematic manner (Tashakkori and Teddlie, 2010). Everyday problem solving includes examination of occurrences from multiple perspectives (Gorard, 2010), incorporating both subjective/social/attitudinal and objective/physical/stable evidence into consideration in finding answers to questions.

Mixture Models in Statistics

This article is a revision of the previous edition article by U.E. Makov, volume 15, pp. 9910–9915, © 2001, Elsevier Ltd.

Abstract

Finite mixtures of distributions have provided a mathematical-based approach to the statistical modeling of a wide variety of random phenomena. They underpin a variety of techniques in major areas of statistics, including cluster and latent class analyses, discriminant analysis, image analysis, and survival analysis, in addition to their more direct role in data analysis and inference of providing descriptive models for distributions.

Introduction

Finite mixture distributions are typically applied to data with two main purposes in mind:

1. to provide an appealing semiparametric framework in which to model unknown distributional shapes, as an alternative to, say, the kernel density method (the set of all normal mixture densities is dense in the set of all density functions under the L1 metric);
2. to provide a probabilistic clustering of the data into g clusters with an outright clustering obtained by assigning each data point to the component to which it has the greatest posterior probability of belonging.

In both situations, there is the question of how many components to include in the mixture.

One of the first major analyses involving the use of mixture models was undertaken over 100 years ago by the famous biometrician Karl Pearson. In his now classic paper (Pearson, 1894), he used the method of moments to fit a mixture of two normal probability density functions with different means μ_1 and μ_2 and variances σ_1^2 and σ_2^2 in proportions π_1 and π_2 to some measurements on the ratio of forehead to body length of $n = 1000$ crabs sampled from the Bay of Naples. The moment estimates of the five parameters in this two-component normal mixture were obtained through the solution of a ninth-degree polynomial (nonic).

Not surprisingly, various attempts were made over the ensuing years to simplify Pearson's moments-based approach to the fitting of a normal mixture model. In the 1960s, the fitting of finite mixture models by maximum likelihood (ML) had been studied in a number of papers, including the seminal papers by Day (1969) and Wolfe (1970). However, it was the publication of the seminal paper of Dempster et al. (1977) on the expectation–maximization (EM) algorithm that greatly stimulated interest in the use of finite mixture distributions to model heterogeneous data. This is because the fitting of mixture models by ML is a classic example of a problem that is simplified considerably by the EM's conceptual unification of ML estimation from data that can be viewed as being incomplete.

Finite mixture models have since been increasingly used to model the distributions of a wide variety of random phenomena and to cluster data sets; see, for example, the recent books by Böhning (1999), Frühwirth-Schnatter (2006), McLachlan and Peel (2000), Schlattmann (2009), and Mengersen et al. (2011), and the references therein. Earlier references on mixture models may be found in the previous books by Everitt and Hand (1981), Lindsay (1995), McLachlan and Basford (1988), and Titterington et al. (1985); see also the papers by Banfield and Raftery (1993) and Fraley and Raftery (2002).

Notation

We let $\mathbf{Y}$ denote a random vector consisting of p feature variables associated with the random phenomenon of interest. We let $\mathbf{y}_1, \ldots, \mathbf{y}_n$ denote n independent observations on $\mathbf{Y}$. With the finite mixture model-based approach to density estimation and clustering, the density of $\mathbf{Y}$ is modeled as a mixture of a number (g) of component densities $f_i(\mathbf{y})$ in some unknown proportions $\pi_1, \ldots, \pi_g$. That is, each data point $\mathbf{y}_j$ is taken to be a realization of the mixture density

$$f(\mathbf{y}_j) = \sum_{i=1}^{g} \pi_i f_i(\mathbf{y}_j) \qquad [1]$$

where the g components correspond to the g groups. In eqn [1], the $f_i(\mathbf{y}_j)$ are densities and the π_i are nonnegative quantities (the mixing proportions) that sum to one. The $f_i(\mathbf{y}_j)$ are called the *component densities* of the mixture.

On specifying a parametric form $f_i(\mathbf{y}_j;\boldsymbol{\theta}_i)$ for each component density, we can fit the parametric mixture model

$$f(\mathbf{y}_j;\boldsymbol{\Psi}) = \sum_{i=1}^{g} \pi_i f_i(\mathbf{y}_j;\boldsymbol{\theta}_i) \qquad [2]$$

by ML via the EM algorithm of Dempster et al. (1977); see also McLachlan and Krishnan (1997). Here $\boldsymbol{\Psi} = (\boldsymbol{\xi}^T, \pi_1, \ldots, \pi_{g-1})^T$ is the vector of unknown parameters, where $\boldsymbol{\xi}$ consists of the elements of the $\boldsymbol{\theta}_i$ known a priori to be distinct.

Identifiability for mixture distributions is defined slightly different. Let

$$f(\mathbf{y}_j;\boldsymbol{\Psi}) = \sum_{i=1}^{g} \pi_i f_i(\mathbf{y}_j;\boldsymbol{\theta}_i)$$

and

$$f(\mathbf{y}_j;\boldsymbol{\Psi}^*) = \sum_{i=1}^{g^*} \pi_i^* f_i(\mathbf{y}_j;\boldsymbol{\theta}_i^*)$$

be any two members of a parametric family of mixture densities. This class of finite mixtures is said to be identifiable for $\boldsymbol{\Psi} \in \boldsymbol{\Omega}$ if

$$f(\mathbf{y}_j; \boldsymbol{\Psi}) \equiv f(\mathbf{y}_j; \boldsymbol{\Psi}^*)$$

if and only if $g = g^*$ and we can permute the component labels so that

$$\pi_i = \pi_i^* \text{ and } f_i(\mathbf{y}_j; \boldsymbol{\theta}_i) = f_i(\mathbf{y}_j; \boldsymbol{\theta}_i^*) \quad (i = 1, \ldots, g) \qquad [3]$$

Here $\equiv$ implies equality of the densities for almost all $\mathbf{y}_j$ relative to the underlying measure on $\mathbf{R}^p$ for $f(\mathbf{y}_j; \boldsymbol{\Psi})$.

In the following, we focus on mixtures of distributions for continuous feature data. But mixtures of discrete distributions, for example, mixtures of Poisson distributions, are also commonly used in practice. Mixtures of distributions for mixed feature data consisting of both discrete and continuous variables are employed too using, for example, the location model (McLachlan and Peel, 2000: Chapter 5).

ML Estimation

The ML estimate of $\boldsymbol{\Psi}$ is obtained as an appropriate root of the likelihood equation

$$\partial \log L(\boldsymbol{\Psi}) / \partial \boldsymbol{\Psi} = 0 \qquad [4]$$

where $L(\boldsymbol{\Psi})$ denotes the likelihood function for $\boldsymbol{\Psi}$ formed from the observed random sample $\mathbf{y}_1, \ldots, \mathbf{y}_n$. Solutions of eqn [4] corresponding to local maxima can be found by application of the EM algorithm. The latter is applied in the framework where an observation $\mathbf{y}_j$ is conceptualized to have arisen from one of the components and the indicator vector $\mathbf{z}_j$ denoting its component of origin is taken to be missing, where $z_{ij} = (\mathbf{z}_j)_i$ is defined to one or zero, according to whether $\mathbf{y}_j$ did or did not arise from the ith component of the mixture ($i = 1, \ldots, g$; $j = 1, \ldots, n$). The complete-data vector is therefore declared to be $\mathbf{y}_c = (\mathbf{y}^T, \mathbf{z}^T)^T$, where $\mathbf{y} = (\mathbf{y}_1^T, \ldots, \mathbf{y}_n^T)^T$ contains the observed data and $\mathbf{z} = (\mathbf{z}_1^T, \ldots, \mathbf{z}_n^T)^T$ contains the unobservable component-indicator variables.

The complete-data log likelihood for $\boldsymbol{\Psi}$, $\log L_c(\boldsymbol{\Psi})$, is given by

$$\log L_c(\boldsymbol{\Psi}) = \sum_{i=1}^{g} \sum_{j=1}^{n} z_{ij} \left\{ \log \pi_i + \log f_i(\mathbf{y}_j; \boldsymbol{\theta}_i) \right\} \qquad [5]$$

The E-step of the EM algorithm requires averaging the complete-data log likelihood $\log L_c(\boldsymbol{\Psi})$ over the conditional distribution of $\mathbf{z}$ given the observed data vector $\mathbf{y}$, using the current fit for the vector of unknown parameters $\boldsymbol{\Psi}$. As $\log L_c(\boldsymbol{\Psi})$, is linear in the unobservable data z_{ij}, the E-step (on the $(k+1)$th iteration) simply requires the calculation of the current conditional expectation of Z_{ij} given the observed data $\mathbf{y}$, where Z_{ij} is the random variable corresponding to z_{ij}. This yields the Q-function given by

$$Q(\boldsymbol{\Psi}; \boldsymbol{\Psi}^{(k)}) = \sum_{i=1}^{g} \sum_{j=1}^{n} \tau_i \left(y_j; \boldsymbol{\Psi}^{(k)} \right) \left\{ \log \pi_i + \log f_i(\mathbf{y}_j; \boldsymbol{\theta}_i) \right\} \qquad [6]$$

where

$$\begin{aligned} \tau_i \left(\mathbf{y}_j; \boldsymbol{\Psi}^{(k)} \right) &= E_{\boldsymbol{\Psi}^{(k)}} \left(Z_{ij} \middle| \mathbf{y} \right) \\ &= \mathrm{pr}_{\boldsymbol{\Psi}^{(k)}} \left\{ Z_{ij} = 1 \middle| \mathbf{y}_j \right\} \\ &= \pi_i^{(k)} f_i \left(\mathbf{y}_j; \boldsymbol{\theta}_i^{(k)} \right) \Big/ f \left(\mathbf{y}_j; \boldsymbol{\Psi}^{(k)} \right) \end{aligned} \qquad [7]$$

is the posterior probability that the jth observation $\mathbf{y}_j$ belongs to the ith component ($i = 1, \ldots, g$; $j = 1, \ldots, n$). In the above, $E_{\boldsymbol{\Psi}^{(k)}}$ and $\mathrm{pr}_{\boldsymbol{\Psi}^{(k)}}$ denote expectation and probability, respectively, using the current value $\boldsymbol{\Psi}^{(k)}$ for $\boldsymbol{\Psi}$.

The M-step on the $(k+1)$th iteration requires the global maximization of $Q(\boldsymbol{\Psi}; \boldsymbol{\Psi}^{(k)})$ with respect to $\boldsymbol{\Psi}$ over the parameter space $\boldsymbol{\Omega}$ to give the updated estimate $\boldsymbol{\Psi}^{(k+1)}$. The updated estimate of the ith mixing proportion π_i is then given by

$$\pi_i^{(k+1)} = \sum_{j=1}^{n} \tau_i \left(\mathbf{y}_j; \boldsymbol{\Psi}^{(k)} \right) \Big/ n \quad (i = 1, \ldots, g) \qquad [8]$$

The updated estimate of the vector $\boldsymbol{\xi}$ containing the distinct parameters in the component densities satisfies the equation

$$\sum_{i=1}^{g} \sum_{j=1}^{n} \tau_{ij} \left(y_j; \boldsymbol{\Psi}^{(k)} \right) \partial \log f_i(y_j; \theta_i) \Big/ \partial \boldsymbol{\xi} = 0 \qquad [9]$$

The E- and M-steps are alternated repeatedly until the difference

$$L\left(\boldsymbol{\Psi}^{(k+1)} \right) - L\left(\boldsymbol{\Psi}^{(k)} \right)$$

changes by an arbitrarily small amount in the case of convergence of the sequence of likelihood values $\{L(\boldsymbol{\Psi}^{(k)})\}$. Dempster et al. (1977) showed that the (incomplete-data) likelihood function $L(\boldsymbol{\Psi})$ is not decreased after an EM iteration; that is,

$$L\left(\boldsymbol{\Psi}^{(k+1)} \right) \geq L\left(\boldsymbol{\Psi}^{(k)} \right) \qquad [10]$$

for $k = 0, 1, 2, \ldots$. Hence convergence must be obtained with a sequence of likelihood values that are bounded above.

As the likelihood eqn [4] tends to have multiple roots corresponding to local maxima, the EM algorithm needs to be started from a variety of initial values for the parameter vector $\boldsymbol{\Psi}$ or for a variety of initial partitions of the data into g groups. The latter can be obtained by randomly dividing the data into g groups corresponding to the g components of the mixture model. With random starts, the effect of the central limit theorem tends to have the component parameters initially being similar at least in large samples. One way to reduce this effect is to first select a small random subsample from the data, which is then randomly assigned to the g components. The first M-step is then performed on the basis of the subsample. The subsample has to be sufficiently large to ensure that the first M-step is able to produce a nondegenerate estimate of the parameter vector $\boldsymbol{\Psi}$.

For mixtures of normal distributions, the choice of root of the likelihood equation in the case of homoscedastic components is straightforward in the sense that the ML estimate exists as the global maximizer of the likelihood function. The situation is less straightforward in the case of heteroscedastic components as the likelihood function is unbounded. In practice, consideration has to be given to the problem of relatively

large local maxima that occur as a consequence of a fitted component having a very small (but nonzero) variance for univariate data or generalized variance (the determinant of the covariance matrix) for multivariate data. Such a component corresponds to a cluster containing a few data points either relatively close together or almost lying in a lower-dimensional subspace in the case of multivariate data. There is thus a need to monitor the relative size of the fitted mixing proportions and of the component variances for univariate observations, or of the generalized component variances for multivariate data, in an attempt to identify these spurious local maximizers.

An account of a Bayesian approach to the fitting of mixture models may be found in Mengersen et al. (2011).

Model-Based Clustering

Once the mixture model has been fitted, a probabilistic clustering of the data into g clusters can be obtained in terms of the fitted posterior probabilities of component membership for the data. An outright partitioning of the observations into g nonoverlapping clusters is effected by assigning each observation to the component to which it has the highest estimated posterior probability of belonging.

With this approach to clustering, the question of how many clusters there are in a data set can be considered in terms of the number of components g in the mixture model. The latter is to be considered on the basis of the likelihood as to be discussed in the next section.

It can be seen that the mixture likelihood-based approach to clustering is model based in that the form of each component density of an observation has to be specified in advance. Hawkins et al. (1982) commented that most writers on cluster analysis "lay more stress on algorithms and criteria in the belief that intuitively reasonable criteria should produce good results over a wide range of possible (and generally unstated) models." For example, the trace $\mathbf{W}$ criterion, where $\mathbf{W}$ is the pooled within-cluster sums of squares and products matrix, is predicated on normal groups with (equal) spherical covariance matrices; but as they pointed out, many users apply this criterion even in the face of evidence of nonspherical clusters or, equivalently, would use Euclidean distance as a metric. They strongly supported the increasing emphasis on a model-based approach to clustering. Marriott (1974) noted that the mixture likelihood-based approach "is about the only clustering technique that is entirely satisfactory from the mathematical point of view. It assumes a well-defined mathematical model, investigates it by well-established statistical techniques, and provides a test of significance for the results."

Choice of the Number of Components

With a mixture model-based approach to clustering, the question of how many clusters there are can be considered in terms of the number of components of the mixture model being used. It is sensible in practice to approach the latter question of the number of components g in a mixture model in terms of an assessment of the smallest number of components compatible with the data. A guide to the final choice of g can be obtained from monitoring the increase in the log likelihood as g is increased from a single component. Unfortunately, it is difficult to carry out formal tests at any stage of this sequential process for the need of an additional component, since, as is well known, regularity conditions fail to hold for the likelihood ratio statistic λ to have its usual asymptotic null distribution of χ^2 with degrees of freedom equal to the difference between the number of parameters under the null and alternative hypotheses (McLachlan and Peel, 2000: Chapter 6).

A formal test of the null hypothesis $H_0{:}g = g_0$ versus the alternative $H_1{:}g = g_1 (g_1 > g_0)$ can be undertaken using a resampling method, as described in McLachlan (1987). A commonly used method of testing the above hypotheses is to adopt the BIC criterion of Schwarz (1978), which, when applied in the present context, leads to H_0 being rejected if twice the increase in the log likelihood (that is, $-2\log\lambda$) has to be greater than $d\log n$, where d denotes the difference between the number of parameters under the two hypotheses. Some theoretical justification for the use of BIC in this role has been given by Keribin (2000). Further information-based criteria for tests on the number of components in a mixture model have been considered (McLachlan and Peel, 2000: Chapter 6), including the integrated classification likelihood (ICL) criterion, as proposed by Biernacki et al. (2000).

Mixtures of Normal and *t*-Distributions

For multivariate data of a continuous nature, attention has concentrated on the use of multivariate normal components because of their computational convenience. Under this assumption, the component densities $f_i(\mathbf{y}_j;\boldsymbol{\theta}_i)$ for $\mathbf{y}_j$ are given by

$$f_i(\mathbf{y}_j;\boldsymbol{\theta}_i) = \phi(\mathbf{y}_j;\boldsymbol{\mu}_i,\boldsymbol{\Sigma}_i) \qquad [11]$$

and $\phi(\mathbf{y}_j;\boldsymbol{\mu}_i,\boldsymbol{\Sigma}_i)$ denotes the p-variate normal density function with mean $\boldsymbol{\mu}_i$ and covariance matrix $\boldsymbol{\Sigma}_i$ $(i = 1,\ldots,g)$. For normal component densities, the updates of the estimates of the component means $\boldsymbol{\mu}_i$ and covariance matrices $\boldsymbol{\Sigma}_i$ are given in closed form.

One attractive feature of adopting mixture models with elliptically symmetric components such as the normal or t-densities is that the implied clustering is invariant under affine transformations of the data; that is, invariant under transformations of the feature vector.

For many applied problems, the tails of the normal distribution are often shorter than appropriate. Also, the estimates of the component means and covariance matrices can be affected by observations that are atypical of the components in the normal mixture model being fitted. McLachlan and Peel (1998) have considered the fitting of mixtures of (multivariate) t-distributions. The t-distribution provides a longer-tailed alternative to the normal distribution. Hence it provides a more robust approach to the fitting of normal mixture models, as observations that are atypical of a normal component are given reduced weight in the calculation of its parameters.

The t density with location parameter $\boldsymbol{\mu}_i$, positive-definite matrix $\boldsymbol{\Sigma}_i$, and ν_i degrees of freedom is given by

$$\phi_t(\mathbf{y}_j;\boldsymbol{\mu}_i,\boldsymbol{\Sigma}_i,\nu_i)=\frac{\Gamma(\nu_i+p/2)|\boldsymbol{\Sigma}_i|^{-1/2}}{(\pi\nu_i)^{(1/2)p}\Gamma(\nu_i/2)\left\{1+\delta\left(\mathbf{y}_j,\boldsymbol{\mu}_i;\boldsymbol{\Sigma}_i\right)\Big/\nu_i\right\}^{(1/2)(\nu_i+p)}} \quad [12]$$

where $\delta(\mathbf{y}_j,\boldsymbol{\mu}_i;\boldsymbol{\Sigma}_i)=(\mathbf{y}_j-\boldsymbol{\mu}_i)^T\sum_i^{-1}(\mathbf{y}_j-\boldsymbol{\mu}_i)$ denotes the Mahalanobis squared distance between $\mathbf{y}_j$ and $\boldsymbol{\mu}_i$ (with $\boldsymbol{\Sigma}_i$ as the covariance matrix). If $\nu_i>1$, $\boldsymbol{\mu}_i$ is the mean of $\mathbf{Y}_j$, and if $\nu_i>2$, $\nu_i(\nu_i-2)^{-1}\boldsymbol{\Sigma}_i$ is its covariance matrix. As ν_i tends to infinity, $\mathbf{Y}_j$ becomes marginally multivariate normal with mean $\boldsymbol{\mu}_i$ and covariance matrix $\boldsymbol{\Sigma}_i$. Hence this parameter ν_i may be viewed as a robustness tuning parameter. It can be fixed in advance or it can be inferred from the data for each component, thereby providing an *adaptive* robust procedure.

Mixtures of Factor Analyzers

For the parametric mixture model [2], it is important that the dimension of $\boldsymbol{\Psi}$ is not large relative to the sample size n. The g-component normal mixture model with unrestricted component-covariance matrices is a highly parameterized model with $\frac{1}{2}p(p+1)$ parameters for each component-covariance matrix $\sum_i(i=1,\ \ldots,\ g)$. Banfield and Raftery (1993) introduced a parameterization of the component-covariance matrix $\boldsymbol{\Sigma}_i$ based on a variant of the standard spectral decomposition of $\boldsymbol{\Sigma}_i$.

A common approach to reducing the number of dimensions is to perform a principal component analysis (PCA) and then to perform the cluster analysis on the basis of the first few leading principal components. But as is well known, projections of the feature data $\mathbf{y}_j$ onto the first few principal axes are not always useful in portraying the group structure; see McLachlan and Peel (2000, p. 239) for an illustrative example of this.

Another approach for reducing the number of unknown parameters in the forms for the component-covariance matrices $\boldsymbol{\Sigma}_i$ is to adopt the mixtures of factor analyzers model as considered in McLachlan and Peel (2000: Chapter 8). With the mixture of factor analyzers model, the ith component-covariance matrix $\boldsymbol{\Sigma}_i$ has the form

$$\boldsymbol{\Sigma}_i=\mathbf{B}_i\mathbf{B}_i^T+\mathbf{D}_i \quad (i=1,\ldots,g) \quad [13]$$

where $\mathbf{B}_i$ is a $p\times q$ matrix of factor loadings and $\mathbf{D}_i$ is a diagonal matrix. It assumes that the component correlations between the observations can be explained by the conditional linear dependence of the latter on q latent or unobservable variables specific to the given component. Unlike the PCA model, the factor analysis model [13] enjoys a powerful invariance property: changes in the scales of the feature variables in $\mathbf{y}_j$ appear only as scale changes in the appropriate rows of the matrix $\mathbf{B}_i$ of factor loadings. If the number of factors q is chosen sufficiently smaller than p, the representation [13] imposes some constraints on the component-covariance matrix $\boldsymbol{\Sigma}_i$ and thus reduces the number of free parameters to be estimated.

The mixtures of factor analyzers model can be fitted by using the alternating expectation–conditional maximization (AECM) algorithm (Meng and van Dyk, 1997). In practice, consideration has to be given to the number of components g and the number of factors q in the mixture of factor analyzers model. One obvious approach is to use the Bayesian Information Criterion (BIC) of Schwarz (1978). An alternative approach is to use the likelihood ratio statistic for tests on g and q. For tests on g, it is well known that regularity conditions do not hold for the usual χ^2 approximation to the asymptotic null distribution of the likelihood ratio test statistic to be valid (McLachlan and Peel, 2000: Chapter 6). This is also the case for tests on q at a given level of g; see Drton (2009).

The mixture of factor analyzers model is sensitive to outliers since it uses normal errors and factors. McLachlan et al. (2007) have considered the use of mixtures of t-analyzers in an attempt to make the model less sensitive to outliers.

Even with the MFA approach, the number of parameters still might not be manageable, particularly if the number of dimensions p is large and/or the number of components (clusters) g is not small (McLachlan et al., 2002). Baek et al. (2010) considered how this factor-analytic approach can be modified to provide a greater reduction in the number of parameters. They termed their approach mixtures of common factor analyzers (MCFA). This is because the matrix of factor loadings is common to the components before the component-specific rotation of the component factors to make them white noise. Recently, Baek and McLachlan (2011) have extended the approach to mixtures of common t-factor analyzers.

In the above, it has been assumed implicitly that there is a one-to-one correspondence between the mixture components and the clusters. With some data, for example, in flow cytometry, the clusters are asymmetric and so each cluster is unable to be modeled adequately by a single component with an elliptically symmetric distribution. One way to handle this situation is to fit mixtures of normal or t-component distributions that are greater in number than that of the clusters; that is, the distribution of the data within a cluster is modeled by a mixture of normal or t-distributions.

Another approach is to fit a mixture model in which each component distribution is chosen to model the data in the corresponding cluster by adopting a mixture model with, for example, skew normal or skew t-component distributions; see Lee and McLachlan (2014) and the references therein.

The reader is referred to the lists in the appendix in McLachlan and Peel (2000) and at http://www.maths.uq.edu.au/~gjm/mix_soft_other/emmix.html for the availability of software for the fitting of mixtures of normal, t, skew normal, skew t, and factor distributions, which includes the EMMIX suite of programs developed initially by McLachlan et al. (1999).

Mobile Communication

Rich Ling, Nanyang Technological University, Singapore

© 2015 Elsevier Ltd. All rights reserved.

Abstract

This article is a review of mobile communication from a social perspective. It sets out a discussion of the definition of mobile communication considering different ways to consider this phenomenon. It is followed by an analysis of current and emerging directions in mobile communication research. This includes an examination of how the mobile phone allows for individual addressability and the interlacing of activities. These characteristics of the mobile phone mean that it can be used for nuanced microcoordination. Mobile communication has been adopted by different groups in different ways. This article examines three of these groups, namely, business use, teens, and among women in developing countries. The article considers the development of location-based services, the ways in which the mobile phone develops social cohesion, and how it is becoming a structural part of social interaction. Finally, the article considers several methodological issues associated with the mobile phone.

Introduction

Mobile communication describes the use of various technological systems in order to communicate while one is away from a fixed location. Mobile communication has been the focus of scholarly work since around 2000 (Green and Haddon, 2009). Researchers in Hong Kong (Leung and Wei, 1999), Finland (Kasesniemi and Rautiainen, 2002; Oksman and Rautianen, 2003), the United Kingdom (Green and Smith, 2004; Grinter and Eldridge, 2001; Haddon, 1997), Japan (Ito, 2001), and Norway (Ling, 2004) as well as many other locations have made contributions. With the development of the mobile Internet, research is starting to bridge the work of the traditional mobile communication community and the Internet research community. This article will examine the definition of mobile communication, the current and emerging issues in mobile communication research, and some methodological issues poised by the study of this area.

What Is Mobile Communication (and What Has It Been)?

A broad definition of mobile communication is the use of a portable communication device to interact with others and eventually with information sources. We likely think of the mobile phone as the most common mobile communication device, but an expanded definition might include the use of semaphore flags, signal lamps, and other portable communication devices. Lars Magnus Ericsson, the founder of the telephone equipment manufacturer Ericsson, mounted a telephone terminal in his car. Using wires to patch into nearby telephone lines he was able to make calls while away from the landline telephone. Following this line of thought, one can think of telephone booths as affording us some type of communication while we are away from our home base (Ling and Donner, 2009). Obviously the phone booth and Ericsson's jury rigged device are only quasi-mobile.

Radio-based wireless devices have allowed for mobile communication for over a century. The work of Marconi gave us the ability to broadcast messages across great distances. Marconi's wireless device was used to communicate long distances using the Morse telegraph code in the late 1800s. As early as 1903, he was sending trans-Atlantic messages. These became mobile when ships installed wireless devices onboard. In the wake of the Titanic disaster in 1912, various legislative bodies enacted laws proscribing the use of radio equipment on passenger ships. In addition, there were moves to regulate the use of radio frequencies.

During the early part of the twentieth century, radio communication moved from transmitting/receiving Morse code to voice. Nonetheless, mobile radio communication was based on broadcasting of a single message to many receivers. By the early 1920s, this developed into commercial radio (Douglas, 1987), and there was also use of radio-based systems for communication by public authorities such as the Detroit Police (Agar, 2003; Farley, 2009; Wikle, 1930). It was also used relatively early by organizations where there was the need to manage a fleet of vehicles such as taxis, delivery trucks, as well as operations in the field such as the military. (In some cases, this was quasi-mobile since it was limited to one-way radio. Upon receiving a message, the driver would have to find a phone booth in order to return the communication.) At this point, radio communication and switched telephony (i.e., the system of connecting two parties through a switching device) lived in two separate worlds. After the Second World War, there was some work done investigating the ability to integrate radio into the switched telephone network (Ling, 2004). The first approach was to use a broadcast system of mobile communication for 'car phones.' This relied on a single antenna that covered a large area. This, however, did not make efficient use of the limited radio capacity. In 1947, Douglas H. Ring and W. Rae Young developed a system that divided the landscape into a mesh of cells that allowed for more efficient use of the limited radio frequencies along with a system with which to hand off the calls between the cells. This system of tracking phones as they moved from one cell to another was first used in a trial developed by AT&T in 1969 on the Amtrak Metroliner train between Washington, DC, and New York in 1969. Eight years later, a system with 10 cells and the capacity for 2000 users was established in Chicago by Motorola. These developments move us closer to what we now call mobile telephony. The cellular

systems allowed for the development of small handsets with which we could call one another whenever we were connected to the system.

The first mobile phones allowed for voice interaction. With time, however, we have added other functionality such as onboard calendars, name registers, and games. In the last few years, this has increasingly included access to a broad variety of online information. One of the first additional communication functions was short message service or texting (Hillebrand et al., 2010; Trosby, n.d., 2004). This function 'pushed' messages to addressees and allowed for asynchronous text-based interaction. Experience shows that there is a niche for this type of interaction. In 2010, there were over 6 trillion text messages sent worldwide.

Mobile phones have developed into sophisticated computing devices that give us access to a wide variety of information sources and ways of interacting with others. Starting with the Japanese iMode system (Lindmark, 2002), the development of the open operative systems that allows us to download a seemingly endless number of 'apps' has led flourishing of smartphones (West and Mace, 2010). In this guise, the mobile phone, along with the Wi-Fi made the mobile phone into a portable Internet device. These devices, along with the larger tablets and other Wi-Fi-enabled devices, allow us to communicate with one another and to search data archives whenever and wherever we might be. They push the definition of communication beyond interaction with other individuals and include interaction with other devices and information sources.

Current and Emerging Directions in Theory and Research

As with the study of many sociotechnical systems, the study of mobile communication's social consequences has seen several deferent phases. The earliest work was often more descriptive and examined adoption by particular groups (Kasesniemi and Rautiainen, 2002; Mante-Meijer and van de Loo, 1998; Rakow and Navarro, 1993). There were also discussions with regards to potential effects of the technology on society (Haddon, 1997; Lange, 1993). Eventually, mobile communication became rather common in the developed world and started to diffuse in developing countries. The growth of adoption in Africa, Asia, and South America led to new analyses. According to his broad investigation of this scholarship, Donner suggests that the early articles examining adoption in developing countries often focused on the determinants of adoption, the impact of mobile use, and/or their role in economic development (2008).

More recently, there has been the development of theoretical insights that again can help in the framing of future analyses (Castells et al., 2007; Geser, 2004; Katz and Aakhus, 2002; Ling, 2008, 2012; Wellman, 2002). Many of these approaches were developed with the assumption that mobile communication was an untethered version of landline telephony with perhaps the addition of texting. The focus is on the effect of mediated person-to-person communication on the lives of individuals. To be sure, this is an important dimension of mobile communication since it has led to many of the issues discussed below. The growth of the mobile Internet and smartphones has added a new wrinkle to the analysis that has yet to be theorized. There are new forms for interpersonal interaction (social networking and interactive games) and the devices can be used to gather information on an 'as needed' basis (e.g., maps for location-based services or medical information in developing countries).

The major questions associated with the study of mobile phones in the social sciences have been associated with the way that they adjust and change social interaction. In some cases, they have facilitated information flow and in other cases they have disrupted the previous communication channels. Research regarding mobile communication has examined how it has

- provided us with individual addressability and interlacing of activity,
- changed the way that we organize social interaction,
- contributed to the development of special cultural formations in different groups,
- developed location-based applications,
- how it has encouraged social cohesion, and
- how it has become increasingly embedded in society.

All the while, one gets the impression that mobile communication research is like chasing a hen with a bushel basket. Researchers keep trying to capture it while it darts and jibes in ever new directions. When we feel that we have captured the essence of mobile communication, there is a new development that gives users new functionality, e.g., the growth of Internet protocol-based texting such as WhatsApp and group texting in Facebook. The users then take these and exploit them in an unexpected direction.

Individual Addressability and Interlaced Activity

Mobile communication has progressively led to the ability to engage in individualized communication since the equipment with which we can communicate has become ever more portable. The first radios required huge steam engines to power them and were only mobile when mounted in, for example, steam ships. Of course the landline system of telephony was available, but it was bound to specific locations. Improvements in technology including, among other things, transistors and the development of the cellular system mean that we have far more sophisticated devices that neatly fit into our pockets or get lost under the stack of newspapers on the kitchen counter. The consequence of these small portable devices is that we are individually addressable. We can call and be called regardless of where we might be. This has, in turn, meant that we can interlace communication with other activities (Ling and Donner, 2009). It also means that we include mediated communication in activities where before we had been incommunicado. On the one hand this leads to an efficiency in planning and the ability to engage in impromptu social interaction with our closest sphere in the folds of daily life (Licoppe, 2004). It also means that we may present a danger to others when, for example, driving (Strayer et al., 2006) and we can potentially drive other copresent individuals to tears with our chatter (Monk et al., 2004).

Microcoordination

Perhaps more than anything else the mobile phone is a coordination tool. Previous to the widespread diffusion of the mobile phone, remote communication took place via the landline telephone. This meant that we called to specific locations on the chance that our eventual interlocutor was nearby. In the case of house-based landline telephones, if we were not able to talk with one person, we might as easily have a conversation with another. This system was useful for coordination, but it did not allow for changes in plans or new arrangements once we – or our eventual conversation partner – were in transit.

The individual addressability of the mobile telephone changed this (Ling and Yttri, 2002). Our newfound ability to communicate while on the run means that we use it to coordinate interactions in at an ever more nuanced level. The ability to make changes in plans or indeed to form plans when away from the landline telephone has changed the way that we coordinate interaction. Many people have only a loose idea that they will, for example, meet friends for a social visit on a particular day. As day arrives and as the eventual meeting partners confirm their interest to meet (perhaps through a series of text messages) the plans begin to take concrete shape. These might include a series of interactions mapping out suggestions (i.e., which café to visit) and negotiating the time. Even as the individuals are en route to the meeting, they might make last minute adjustments (i.e., the first person to the café finds it too crowded and thus suggests a 'plan B'). The individual addressability provided by the mobile phone allows for the ongoing negotiation of meetings and also the discussion of family logistics. One partner who is late from a meeting might call or text to the other who can then shuffle the order in which they pick up the kids at school or go shopping.

This type of give-and-take in the planning process works in the context of small groups since the individuals can interact and form plans and the situation clarifies itself. It is clear, however, that this type of planning is not suited to the functioning of large organizations. In that case, time-based coordination retains its place. Interestingly, however, use of the mobile Internet via smartphones allows the development of applications where people can access timetables for these organizations. Apps that give the real-time bus schedules for the nearest bus stop or the departure time and gate number for a particular flight give us individualized access to this information and facilitate the coordination through the diffusion of information.

Mobile Communication among Particular Groups

Mobile communication has been variously adopted by different groups in a variety of locations. This variation in adoption has itself been a topic of research. Some have examined how it varies from place to place (Campbell and Russo, 2003; Lasén, 2004) while others have noted that it unifies behavior (Katz and Aakhus, 2002). There are several groups that have had particular adoption patterns.

Business and Formal Organizations

Radio communication has a long history in commercial and formal organizations. As noted above, broadcast radios were used by organizations that needed to organize a large number of vehicles with a constant flow of shorter tasks such as local delivery companies, taxis, or large animal veterinarians who need to visit a variety of locations (Ling, 2004). As with the police and fire, these organizations used a central dispatching system via broadcast radio.

With the coming of the mobile telephone, the broadcast radio system was to some degree displaced (Manning, 1996; Townsend, 2000). Another group who quickly adopted the mobile phone was sales people who often needed to work out complex meeting schedules in a variety of locations (Ling, 2012). The device facilitated coordination and it allowed employees who were out in the field to, for example, call their warehouse to check on the availability of goods. The mobile phone also was adopted by construction workers in order to facilitate the sharing of equipment and interaction with, for example, architects when the plans do not fit the situation at the building site. With time, the mobile phone has also become a way for employers to contact substitutes when, for example, a shift worker calls in sick. In other cases, organizations that have adopted open office solutions with 'hot desking' may use a variety of different work stations from day to day or even hour to hour. In order to facilitate this, they equip all employees with mobile phones (Julsrud, 2005).

The effect of mobile communication on commerce can also be seen in developing countries. In these cases, the coordination might have to do, for example, with the local production of handcrafts (Jagun et al., 2008), everyday logistics (Sey, 2011), or facilitating the flow of market information (Franklin et al., 2000; Jensen, 2007; Platteau and Abraham, 1987; Rahman, 2007). In developing countries, entrepreneurs and customers might also work out special uses of the mobile phone to facilitate commerce. One approach is to use 'beeps,' 'flashes,' or missed calls in order to signal potential work. In this system, a person who, for example, needs the help of a plumber or carpenter or needs to summon a taxi will call the number, let it ring once or twice and then hang up. Because of caller identity, the handworker or driver has the number of the potential client. If they are available for the work, they can call back and make the specific arrangements (Donner, 2007; Geirbo et al., 2007).

Teen Use of Mobile Communication

Another specific group that has adopted the mobile phone is teens. The device fits particularly well into their lives and indeed this group was one of the first to adopt it for largely social purposes. With the development of prepaid subscriptions that set boundaries on consumption, teens were soon among the most enthusiastic users of mobile telephony (Johnsen, 2003). The analysis of teens' use of mobile communication has described its contribution to a sense of teen culture (Goggin and Crawford, 2011; Ito et al., 2005). Following a slightly different direction, there has also been analysis of how mobile communication ebbs and flows as teens move through the different phases of adolescence (Helles, 2009; Ling, 2010). There has also been analysis of how the mobile phone plays into the sense of teen self-image (Skog, 2002) and how texting becomes a way for teens to exploit the plasticity of the language (Baron and Campbell, 2010; Baron and Ling, 2011; Ling et al., 2010). (This is also something

that is possible to see in texting in developing countries (Vold Lexander, 2011).)

By 2011, teens in the United States were among the most enthusiastic users of texting. Analysis by Lenhart shows that teens aged 14–17 years sent a median of 60 texts per day (2012). The fact that teen girls in the United States send a median of 100 texts per day shows that they are perhaps more committed to texting than are boys. Regardless of gender, texting is one of the most important communication channels for teens. According to Lenhart, there are 63% of teens who report using it daily to stay in touch with friends. Only 39% call using the mobile phone, 35% have face-to-face talks (outside school) and 35% use social networking sites. The data show that only 19% use the landline phone and 6% e-mail one another. Texting and talking are shown to be complementary, not competitive forms of communications since the heaviest texters also talked the most.

Women in Developing Countries

Women in developing countries have also seen changes in their situation as a result of the mobile phone. For some it has been a source of income and for others it has facilitated their daily lives by providing a way to coordinate time-consuming tasks. For the women who have had to find work far from home, it has given them a way to stay in contact with their families and the mobile phone has become an element in their interactions with men.

Perhaps one of the first ways we saw the effect of the mobile phone on women in developing countries was in the case of the Grameen Phone 'Village Phone' program. Grameen Phone provided women in rural Bangladesh with microloans to purchase mobile phones and a solar battery charging system that became a privately owned, publically available telephone link for their village. The 'telephone ladies' paid back their loans and eventually derived a profit by charging other villagers for calls (Aminuzzaman et al., 2003; Richardson et al., 2000). In 2003, it was estimated that there are more than 21 000 women using this system in Bangladesh (Yunus, 2003). Since that time, handsets have become less expensive and more people have the ability to own their own handset.

The mobile phone provides women in developing countries with a communication channel through which they can experience not only increased empowerment (Lee and Jayachandran, 2009) but also new forms of control. Women who move away from their home also use the mobile phone for a variety of both social and instrumental tasks. Madianou and Miller, for example, describe how the mobile phone allows Filipina women working in London to maintain contact with their children who live in the Philippines (2011). The separation from their children is bridged, to some degree, by using the phone to call and to maintain contact. Another example of this is seen with women who are 'internal migrants' in China. They leave their village of origin to work in the larger cities. Following the work of Wallis, the mobile phone becomes an important channel for these women to maintain contact with their families and to organize their social lives in the cities. However, the mobile phone is also a conduit through which employers can reach into their private lives and surreptitiously check up on them (2011). Thus, there is both empowerment and disempowerment packaged into the mobile phone for these women.

Another way that mobile telephony is coming into the lives of women (and for that matter men) in developing countries is through the growth of mobile-based health initiatives. Mobile-based medicine (or m-health) allows local health care givers, who are in many cases women (Chib and Hsueh-Hua Chen, 2011), to get advice from more central health care providers and it also can streamline reporting in health information systems. Rather than relying on cumbersome paper-based systems that needs manual aggregation, mobile handsets allow the development of broad-scale health reporting systems (Asangansi and Braa, 2010).

Beyond these more instrumental uses, the mobile telephony is also used in the personal interactions of women and men. As in developed countries, it is used to facilitate romantic interactions. As we might expect, its use can also lead to misunderstandings (Archambault, 2011). In some cases, the mobile phone can undermine traditional forms of matchmaking (Ellwood-Clayton, 2005). Also, since it can be used in what is seen as a subversion of long-established authority roles in these affairs, it can be a particularly contentious object that needs to be hidden by the teen girls when they receive it as a surreptitious gift from a boy (Hijazi-Omari and Ribak, 2008). Finally, in a less savory combination of romantic relationships and mobile phone-aided entrepreneurship, Horst and Miller document how impoverished women in Jamaica use the phone in order to maintain an overview of potential sexual partners who would also then contribute to their household economy in a type of informal prostitution (2005). Thus, in a surprising variety of ways, mobile communication has been adopted by women in developing countries. In many cases, it empowers them but it is also used to maintain existing exploitive power relationships.

Location-Based Services

Since their inception, mobile phones have included a location-based dimension in their use. Early users could remind interlocutors about their location and gather information on where, for example, a meeting was or where they might find a particular location (Elliott and Urry, 2010). More recently, the integration of location determination functionality in mobile phones (i.e., use of the Global Positioning System) along with mapping software has led to the development of a variety of applications or apps. These facilitate finding, for example, stores or services (i.e., taxi stands or bus stops). In addition, there are apps that help tourists find hotels, restaurants, and sights along with others' evaluations.

Another use area is location-based social networking (Gordon and Silva, 2011) that allow people to follow the movement of friends or to compare 'check-ins.' There can be gaming aspects to this type of mobile application (i.e., Foursquare) or they can simply be a way for us to follow one another as we move through the day (Google latitude). There are also various types of location-based games (i.e., BotFighters) and hobbies (geocaching). This type of location based-service is perhaps the most commonly discussed in the media. It is also interesting to note that use of these services is relatively low. According to Lenhart, their use in 2010 was below 10% of teens (Lenhart, 2012). Other forms of location-based activities include attaching information to places.

Finally, a more instrumental version of location-based mobile communication is the tracking of objects. This can include, for example, tracking railroad cars, freight trucks, or shipping containers as they move toward their destination. At a smaller scale, it can include tracking the progress of particular products or parts in a 'just in time' assembly line. This type of application moves away from interpersonal interaction and focuses more on facilitating logistics in complex organizations. (This can include using the mobile phone system, the GPS system, or some combination of the two.)

Social Cohesion

There has been much discussion asking whether Information and Communications Technologies (ICTs), including mobile phones, have reduced the size of social networks and led to social isolation (McPherson et al., 2006; Putnam, 2000). To this point, research on mobile communication has showed that, in many cases, it has a positive effect on social cohesion. This includes work on families and friendship groups in Scandinavia (Ling, 2008; Ling and Stald, 2010), work by Kim et al. in Korea (2006), Matsuda in Japan (2005: p. 127), and Smoreda and Thomas in Europe (2001). Matsuda describes what she calls the 'full time intimate sphere' (2005: p. 133), Habuchi describes the tele-cocoon (2005: p. 167), and Licoppe gives us the idea of connected presence (2004). All of these concepts suggest that the device is a tool of the intimate sphere. Castells et al. (2007), Miyata (2006), Igarashi et al. (2005), Ishii (2006), Reid and Reid (2005), and Hampton each discuss the way in which social cohesion is developed and maintained via the mobile phone. Hampton et al. show that mobile phone use increases the size of an individual's core social network (2011). That being said, this is still a limited number of people. In a study of machine-generated calling logs containing approximately 65 million calls and texts in Norway, Ling, Bertel, and Sundsøy find that half of all text and calls commonly go to less than five different other numbers (2012). In sum, it is fair to say that the mobile phone helps to maintain social cohesion in the intimate sphere.

Structural Embedding of Mobile Communication in Society

Much of the discussion of mobile communication is framed in the affordances, the benefits, and the costs at the personal level. Another approach is to look at the social effect of mobile communication. When looking more broadly at the social level, it is clear that the mobile telephony provides social utility for the group. It facilitates coordination, helps maintain cohesion, and is a safety channel in the case of emergencies. In order to function in this way, however, it assumes that the individual has a functioning device.

As with, for example, fax machines in their day or office calendar programs, adoption of the mobile phone by a group of people facilitates the functioning of the group. The fax (that was subsequently replaced by e-mail and scanners), the electronic calendar, and the mobile phone provide a common platform for different types of information sharing. These systems, however, do not come without a cost to the individual. We have to take the time to learn how to use the system and, in some ways, we have to surrender our individual prerogative to participation with others in use of the system. Not having the equipment or not using the program places us outside the group. In the case of the mobile phone, there is also the cost and the maintenance of the handset just as there is the cost of the subscription. The worldwide adoption of mobile telephony shows that we are willing to incur these costs in order to be linked into our social networks.

If one does not have a mobile phone; if it is forgotten at home, turned off, or not charged then the individual becomes a broken link in the social network. In this case, we have, in a small way, failed our friends and family who rely on being able to contact us. To the degree that we can no longer make agreements or coordinate interaction we have failed our social obligations. The mobile phone has become, to some degree, a structural part of society.

Methodological Issues

Studying mobile communication has relied on the traditional approaches to examining social phenomena. There have been many qualitative analyses including observation studies, focus groups, and person-to-person interviews. In addition, there have been a wide variety of surveys. These analyses have given us insight into how people use their mobile phones, the differences between cultures in use and the ways that people adapt and change the technology to better fit with their social context. They have given us insight into how quickly the devices have spread and also an understanding of the social consequences of mobile phone use.

These research tools have their role, and they also have their weaknesses. Qualitative analyses give us fine-grained insight into specific situations. However, the results are rarely generalizable. We may glean deep awareness of how a particular group uses mobile phones, but since the sampling is limited and not randomized, we need to be cautious with regards applying the insights into other situations. By contrast, surveys can give generalizable insight, but they too have their limitations, particularly in the case of quotidian activities such as mobile communication. It is often difficult for people to remember, for example, how many calls they made during the day. Indeed, comparisons of survey material with call data records show only moderate correlation (Boase and Ling, 2011). This might argue for using machine logs in order to measure behavior. The weakness of this approach is that we do not necessarily know the attitudes or demographics of the users. Thus, all the methods to study mobile communication have their potentials and their limitations. Indeed mobile communication presents public opinion researchers with a new set of difficulties (Groves, 2011).

Another potential, however, is to use mobile phones as data collection devices. On-board logging of activities is one approach. Another is to use the individual addressability of the mobile phone to carry out real-time research. Kubey, Larson, and Csikszentmihaly have suggested using pagers in their experience sampling method (1996). Since then, mobile phones have been examined in relation to their use as probes to measure real-time automobile traffic (Rose, 2006), health-related behavior (Hicks et al., 2010), and interviewing in situ for auditing decision making (Baxter and Hunton, 2011).

Mobility and Travel Activity Patterns

Abstract

Mobility refers to a range of phenomena at a range of spatial and temporal scales. It typically refers to the movement of people. If this movement is permanent, it falls into the topic of migration. If it is voluntarily carried out for recreation, it may be tourism. At more local scales it is a necessary component of daily life, whether as commuting to work or in order to carry out other daily activities. Mobility is an important topic in the field of transport geography and touches on many methodologies. It is fundamental to the study of spatial interaction between places and the study of flows of people and goods.

Mobility refers to a range of phenomena at a range of spatial and temporal scales. It typically refers to the movement of people, including migration, trips by tourists, and commuting trips. Migration refers to permanent or long-term movement by people, usually associated with a new home location that is relatively far away (e.g., in another city) from the original home location. It has been and continues to be a major reason for changing spatial patterns of population. It may be voluntary, often for economic motives, or involuntary, as with refugees or slaves. Seasonal migration, such as for farm labor, may be a recurring pattern or migration may be permanent, as with settlers moving to a new country. It is common to speak of push and pull factors in such cases, with push factors being those that encourage people to leave a particular place and pull factors those that attract migrants to an area. Economic motives can be important to both push and pull factors. In the twentieth century, rural to urban migration and suburban migration have become important sources of change in population patterns. The US decennial census records current household location and the previous location 10 years ago; this provides the principal source for understanding migration within the country at interregional and intrastate scales. In other countries, data on migration can be very difficult to obtain and may not exist.

Tourism can be defined broadly as travel for recreational purposes, whether local, domestic, international, or even into outer space. It is an important economic activity in many areas. Tourism is a relatively recent phenomenon and has been highly influenced by improvements in transport technology/space–time convergence. It is a type of mobility expected to grow in magnitude, at least in the developing world, but with uncertain socioeconomic and environmental impacts. Recent studies have examined the mobility patterns of tourists using global positioning system (GPS) data and advanced analytical methods such as sequence alignment and Geographic Information Systems (GIS)-based visualizations (e.g., Shoval and Isaacson, 2007). These studies observed distinctive patterns of visits (in terms of the order in which tourists visit a set of sites) and routes for different social groups.

Daily Mobility

Daily mobility falls within the field of transport geography and it is at the local level where the movement of individual and households has been most intensively studied. The study of individual activity–travel patterns has been an important topic since the 1960s. Major objectives of this area of study are to examine how people make decisions about destinations, transport modes, and trip chaining. One finding is that the household level is absolutely essential to understanding people's daily mobility, as an individual's ability or need to travel is dependent on various household activities and other demands on travel resources (Hanson and Hanson, 1980; Kwan, 1999).

The daily commute to and from work is the most studied component of activity–travel behavior because traditionally it has been the primary source of road congestion and therefore the primary focus of urban transportation planning models; commuting is also the form of daily travel that is most easily measured due to the availability of decennial census data up to the 2000 Census and subsequently the American Community Survey. In this case mobility is treated as a derived demand, dependent on the need to travel out of the house to a workplace. Standard urban models incorporate mobility in the form of commuting. These models are based on an economic trade-off between commuting costs (increasing with distance from the center of the city) and housing prices (decreasing with distance from the city center). Different households will choose different locations based on their abilities to pay and household priorities (Alonso, 1964). In this monocentric urban model, land use is based on the spatial mobility of workers. Mobility is assumed to be identical for all people, and treated largely as the equivalent of distance. Actual commuting behavior suggests that few people try to minimize their distance to work by relocating their homes or workplaces (Clark et al., 2003). Such residential relocation is not necessarily easy or simple.

Congestion is a consequence of too much mobility and limited transport capacity. It reduces mobility for certain modes at certain times of the day and week. Over the long term, congestion could reshape urban patterns by encouraging people to move their homes or workplaces to maintain their commuting time. However, in recent decades it has been noted and debated that commuting times are not increasing as would be expected given the increasing population of large cities in the US. This has been termed the commuting paradox (Gordon et al., 1991), and is explained, in part, by the

 http://dx.doi.org/10.1016/B978-0-08-097086-8.72093-9

development of polycentric or decentralized cities in which more people may live closer to their place of employment than possible in a monocentric city. Maintaining reasonable levels of mobility is a powerful, if unexamined, goal for households. In fact, a law of constant commuting time (Hupkes, 1982) has been specified, which notes average times allotted to commuting have remained surprisingly constant over time and across many transport modes.

Activity–Travel Patterns and Automobility

The activity-based approach became important in the 1970s. This is based on the idea that travel is not usually undertaken for its own purpose but reflects a need to carry out particular activities (Jones et al., 1983). Any understanding of a person's travel patterns must be based on his or her activity patterns. These activities are part of an agenda of things a household must do. These activities may or may not require travel, and if they do, it may be carried out in a variety of ways. The scheduling and implementation of activities will create a need for travel.

Studies of activity–travel patterns stemmed from dissatisfaction with metropolitan transportation planning that was based on aggregated data representing census or planning zones. These data are often based on census household data, which provide average commuting data by zone. The Census Transportation Planning Products also provides some additional aggregate flow data. Data for individual travel behavior are more limited. The US Department of Transportation collects a National Household Travel Survey data set from a small number of households nationally. Much of the data available about individual household mobility come from disaggregate travel diary surveys collected at the level of individual metropolitan areas. These are collected from a representative sample of households in a particular city, and record each activity each person engaged in, when, for how long, whether travel was involved, and if so, details of the trip. These data sets have provided tremendous insights into mobility, especially when used with GIS. In the last decade or so, regional planning agencies in the U.S. and transport researchers have started to collect data of people's activities and movement with GPS or other location-aware wireless technologies. These high-resolution space–time data have encouraged the development of new analytical methods that enable researchers to yield new insights about people's activity–travel patterns (Shen et al., 2013).

The mode of transportation available is an important factor to mobility. For many in the developed world, automobility is the predominant form for more than very short travel, and may be the only mode feasible in many cases. In the developed world, the rise of car ownership is the predominant factor in understanding mobility changes. Statistics such as those on vehicle miles traveled show that increasing car ownership and car use have increased the average number of miles that people travel. Intelligent transportation systems are a broad range of technologies that have been deployed to help preserve or improve mobility by car (Figueiredo et al., 2001). Public transit systems are found in cities of all sizes and in rural areas, but the vast majority of ridership is accounted for by the largest cities (American Public Transportation Association, 2013). Those who do not possess or are unable to use a car may be completely dependent on transit ('captive riders') for any trip outside their immediate neighborhood (Rutherford and Wekerle, 1988).

Mobility is not equally distributed among the population. Women have shorter commutes and typically travel shorter distances than men (Hanson and Pratt, 1988). This has been explained in various ways that are based on their typically greater household responsibilities and lower salaries. As mobility in developed worlds is strongly dependent on income, which often follows divisions of race and ethnicity, minority populations often have lower levels of mobility due to reduced access to cars (Johnston-Anumonwo, 1997; Lee and Kwan, 2011).

Another group with low levels of mobility is children. Children also have decreasing levels of mobility in many developed countries, as parents increasingly restrict their independent mobility to areas within the neighborhood or around the home due to fear (O'Brien et al., 2000). Neighborhoods are designed around the needs of automobiles and drivers and may not be safe for pedestrians or bicycles. Children in these areas may be restricted to a small area unless accompanying a parent in a car. While generations of children walked to school in the past, the journey to school has become increasingly reliant on buses or parent's motor vehicles (McMillan, 2005).

The elderly face mobility limitations for physical or mental reasons as well as their frequent inability to make use of automobiles (Shoval et al., 2011). Impaired mobility, especially physical reasons preventing walking, is a serious health problem for the elderly, and a decrease in mobility can swiftly be followed by health declines. The disabled may be physically limited in their mobility at very local scales, such as individual buildings, though they have been successful in improving their mobility through legislation.

Differential mobility, or the lack of mobility, has been implicated in several urban issues relating to employment. Spatial mismatch refers to a condition in which low-mobility populations, typically minority workers, in central city locations are unable to reach suburban employment locations. The decentralization trends, which have maintained stable automobile-based mobility, have shifted employment away from older walking and transit-based neighborhoods to newer automobile-oriented suburban areas. Those workers who lack social mobility and limited physical mobility are effectively trapped in areas with few jobs. They face a mismatch between their home locations and that of potential jobs (McLafferty and Preston, 1996).

Spatial entrapment refers to a phenomenon in which women, who commonly have less mobility due to financial constraints and household responsibilities, are limited in their ability to seek employment far away from home. Employers may take advantage of this and locate facilities in suburban locations where they can tap into this relatively immobile workforce (Nelson, 1986). Social exclusion is a phenomenon in which certain populations are not able to participate fully in society or are excluded from accessing important services. This may be due to a variety of factors including discrimination, socioeconomic differences, language, but also a lack of

mobility. Enabling greater mobility by immobile populations has therefore become an important goal.

Conceptualizations of Human Mobility and Activity–Travel Patterns

Distance is an increasingly small factor in understanding human mobility. New transport and communication technologies have vastly restructured the importance of distance as a deterrent to travel or interaction (Kwan and Weber, 2003). At one point, the death of distance was forecast, but travel has continued to increase despite the widespread ability to substitute virtual travel for physical mobility. Improved information and communications technologies will reduce constraints on mobility. GIS and related technologies have greatly increased the ability to measure, analyze, and visualize human mobility. The ability to work with data sets with large numbers of individuals and locations and connect locations through network space with dynamic travel times has greatly enhanced our understanding of human activity–travel patterns. Mobility is important to space–time accessibility, but the availability of destinations or opportunities is also important. An individual's mobility may be very high at night, but if few destinations are open, it is of little importance.

An important framework for understanding mobility is time geography (Hägerstrand, 1970; Kwan, 2004). This was put forth by Torsten Hägerstrand in 1970 and has been further developed by many others. The time–geographic framework examines individual activity–travel patterns during the course of a day or some longer period. While many approaches to mobility focus on enabling technologies, time geography is oriented toward constraints on mobility. These are typically described as physical and biological limits to mobility, limits due to authority (explained below), and those related to an individual's schedule of activities and need to coordinate tasks at different places at different points in time.

Physical and biological limits are straightforward. Humans are likely to travel at only 3–4 miles per hour (4–6 km h^{-1}) on foot for fairly short distances. Sleep, food, and other bodily functions must be attended to at regular intervals. Use of mechanized transport will greatly speed up travel, but there are still limits. Individuals will vary widely in their physical limitations or tolerances, and even more widely when age, gender, and disability are taken into account.

Authority limits to mobility exist because individuals do not have the right to go anywhere at any time, even in a free society. Access may be restricted to property owners, employees, or those with the proper permission or security clearance. The authority may be formal or customary, or reflect a fear of consequences. Totalitarian countries may have significant limitations on the right to move freely, and the ability to freely pass between countries has always been restricted. Even where mobility is relatively unrestricted it will still be subject to regulation, as with speed limits on highways. Authority constraints are likely to be fairly uniform across the population in an egalitarian society, but there will always be situations in which certain individuals have greater rights or fewer restrictions than others.

Coupling constraints refer to the limits on mobility resulting from a person's need to undertake joint activities with other individuals (e.g., a meeting) at particular times and places. This constraint reflects the fact that individuals do not possess complete control over their own activities and are likely to be involved in fixed activities, those for which the individual cannot modify the location and timing. These fixed activities provide the framework for their daily activity schedule (Weber and Kwan, 2002). Any other activities that an individual desires to pursue and has the ability to choose times and locations are flexible activities. Flexible activities can be carried out only if they are feasible given the times, duration, and location of fixed activities. The classic case involves an individual who wishes to leave his or her office during a lunch break, and is limited to potential restaurants that can be reached and the food eaten within the time available. The number of potential restaurants will be highly variable among individuals depending on their typical activities and the area in which they live. It will be further modified by individuals' incomplete information about travel times and locations, as well as the uncertainty or unreliability of travel times.

An important factor in understanding mobility is the phenomenon of space–time convergence or compression (Janelle, 1969). This was identified in the 1960s and refers to decreasing travel times between places due to improved transportation, such as jet planes or long-distance freeways. Higher speeds and/or shorter routes decreased travel time between cities, essentially bringing these places closer together. Much of the story of space–time convergence is that of transportation technology innovations, but there are important social and economic consequences. The phenomenon of jet lag is a physical manifestation of convergence, and the finding of constant commuting times is another. Travel times between places may increase due to a deterioration of transport facilities, increasing congestion, or political disruptions. This is space–time divergence. This has been observed in Central Africa and North Korea where mechanized transport systems have deteriorated and walking has once again become the predominant mode.

The importance of the personal automobile to mobility in developed countries, and especially the US, has led to concerns that people are too dependent on cars for mobility.

Mobility has therefore become an important topic in urban design. A debate exists as whether cities in developed nations are too dependent on automobility. This may create a health problem to individuals due to reduced exercise and to society in the form of pollution and reliance on nonrenewable fuels. It may be that people in developed countries possess too much mobility, or at least mobility that is dependent on nonrenewable fuels and creates considerable pollution. The concept of sustainability evaluates whether a practice can be continued in the long term, and automobile-based mobility in its present form is not considered sustainable. This view has led to frequent calls to reduce auto use and redesign society around other forms of transport, typically transit, though the sustainability of transit is itself questionable without new fuels and large numbers of passengers. The concept of excess commuting measures the extent to which observed commuting patterns and distances are near the minimum theoretically possible (Giuliano and Small, 1993). Others seek to promote more

basic types of mobility, such as bicycling and walking. These forms of active transport have benefits both for transportation as well as personal health. Those who defend the role of automobiles in US society may describe their role as preserving mobility, which has come to be viewed by many as a basic right.

In recent years a 'new mobilities paradigm' has emerged based on the work of sociologists, geographers, and transport researchers. It asserts the ontological significance of the movements of people, goods, and information, and challenges the conventional notion that places and regions are stable entities whereas movements are transient and analytically unimportant (Urry, 2007). The paradigm emphasizes that all places are connected by networks of movements and flows (which human geography has recognized since the 1940s), and that the time people spend on traveling is not dead time that they always seek to minimize.

Abstract

Social mobility is the movement in time of individuals, families, or other social units between positions of varying advantage in the system of social stratification of a society. Classical authors have studied social mobility primarily in its contribution to class or status group formation. Recent research concentrates on identifying the degree to which individuals' social opportunities in life are conditioned by their social origins (conditions of life in the parental family) and on specifying the individual, institutional, and societal factors responsible for it. Studies of the process of status attainment show that the social status or prestige level of a job attained by a person at a given point in his or her career strongly depends on earlier job achievements, educational qualifications, and parents' status. Studies of intergenerational class mobility analyze the patterns of transition from parental (origin) class to individuals' own (destination) class and show that class destinations heavily depend on class origins. While, in general, a high degree of constancy over time and cross-national similarity among economically advanced societies is found in relative rates of mobility, social fluidity has slightly increased in some societies in recent decades. Absolute rates of mobility vary more than relative rates across societies and time, yet have partly converged between societies in recent decades.

Social mobility is the movement in time of social units between different positions in the system of social stratification of a society. The moving units are usually individuals, but may also be groups (families or kinship units). Society is seen as comprising at any given time an ordered system of more or less fixed positions that individuals or groups can hold and potentially move between. The system is stratified to the extent that (1) the positions are more or less advantageous and provide their holders with unequal power, material or symbolic means, and privilege; (2) individuals or groups have different chances of access to or movement between the positions of unequal advantage. This second aspect represents the core domain in the study of social mobility.

Social mobility research distinguishes between *inter*generational and *intra*generational mobility. *Inter*generational mobility compares individuals' positions in adult life with the positions of their families of origin; *intra*generational (or career) mobility studies position sequences within individuals' own generations (life-time), for instance, the moves between the successive jobs in working life. To assess social mobility, researchers distinguish between absolute rates and relative rates of social mobility (replacing older concepts of structural and exchange mobility). Depending on the research tradition, scholars exploit different concepts of social stratification (class, prestige, status, income), and they use different units of analysis (individuals, couples, households, or larger groups).

Research Questions and Traditions of Study

Classical authors have primarily seen social mobility or immobility as a mechanism of *class or status group formation*. The basic assumption is that classes, status groups, or other collectivities with some form of sociocultural or sociopolitical identity can only emerge and potentially provide a basis for collective action on condition that they achieve a sufficient degree of 'demographic identity' (Goldthorpe) in their membership, that is, when they include a kernel of members homogeneous in terms of their social origin and stable over time (families across generations or individuals through their working lives). Along these lines, Marx – whose main concern with mobility is otherwise with *collective* downward mobility of small proprietors and other middle classes into the proletariat – considers *individual* mobility or immobility as a crucial determinant of working-class organization in his discussion of the North American class structure. Contrary to Europe, classes in America, he argues (much like does later Sombart), "have not yet become fixed, but continually change and interchange their elements in a constant flux" (Marx, 1958: 225). While mobility weakens class formation in the working class, the rule of the ruling class is stabilized by assimilating 'the foremost minds of a ruled class.' Also stressing the connection to social mobility, Max Weber even defines a social class as an ensemble of those class situations among which high interchange of individuals typically takes place. But intergenerationally, Weber argues, the possibility of upward social mobility is limited and even decreasing.

After World War II, research on social mobility has largely turned to the study of *social opportunity*, aiming to determine the relative openness or rigidity of the stratification system concerning access to positions of varying advantage. Research has in particular concentrated on identifying the degree to which individuals' prospects in life are determined by the social conditions of their family of origin and on specifying the individual, institutional, and societal factors responsible for it. The more strongly the positions persons hold are conditioned by their social provenance, the more rigid and closed is a stratification system; the greater the mobility between social origin and a persons' own position, the more open or fluid that system is.

Issues related to social mobility are often the object of normative and political discourse and are then often interpreted ideologically, for instance, as ways of legitimizing social inequalities. In this vein, variants of liberal political philosophy from John Stuart Mill onward regard unequal conditions as legitimate when they result from (fair) competition or when unequal chances of access to privileged positions are due to unequal achievements. In its extreme form, the *functionalist theory of stratification* (*see* Social Stratification) holds unequal rewards to be deserved as they are assumed to be distributed according to the contributions made to the efficient functioning (and ultimately survival) of society and are thought to be necessary to attract the most able and hard-working individuals to the most important positions. Though at times influenced by normative preferences, research in the field is analytical and empirical. Its results may, however, serve to examine to what degree and for what reasons social reality conforms to or falls short of particular normative or political goals.

The investigation of social mobility is mainly pursued by way of observation and comparison of national populations. Comparative designs are essential to determine the extent to which openness or rigidity of the stratification system is related to other characteristics of societies. Macrotheoretical approaches highlight characteristics such as the degree of societies' modernity, their economic and political order (e.g., capitalist market vs state command economies), particular institutions or policies. Research has especially focused on the evolution of social mobility in line with the development of industrial society. Notably, with the transition from preindustrial to industrial society, a *historical increase* in mobility has been assumed, either as a precondition for the take off of industrial development or as its consequence (Lipset and Zetterberg, 1959); others assume a *steady increase* in mobility as industrialism advances and an increasing *uniformity* and *convergence* of social structures and social mobility in industrial societies, due to standardizing tendencies inherent in advanced technologies and other elements of industrialism. Finally, *exceptionally* high rates of mobility have been postulated for specific societies, particularly those not burdened by the legacy of the European feudal past or its class-based stratification system, such as the United States, Australia, or Japan. To test such hypotheses, numerous data sets in many different societies have been created, primarily through large-scale population surveys, but also (notably in studies on earlier periods) by using suitable information from official records.

For the purposes of a structured summary, much of the literature can be represented as a debate between two different paradigms and research traditions. To study mobility, both essentially rely on work positions, that is, the (occupational) jobs individuals hold to earn a living. The *status attainment* approach, on the one side, sees the principal property of these jobs in terms of their respective location in a finely graduated continuum of rewards related to the position and conveyed to their incumbents. The continuum of rewards is generally conceived in terms of social prestige or socioeconomic status and measured by corresponding scales (*see* Social Stratification). The *class mobility* approach, on the other side, conceives the (structure of) positions among which mobility can occur as discrete classes, which differ from each other by properties of a qualitatively different nature rather than along one single vertical dimension only. In earlier studies, categories consisted of rather broad groupings of occupations defined in an ad hoc manner (sometimes as broadly as farm/manual/nonmanual). More sophisticated class schemas are grounded in theoretically comprehensive conceptions of the class structure. In their now widely accepted class schema, Erikson and Goldthorpe (1992) draw on the character of the employment relations as core criterion to identify different classes, in addition to the criterion of ownership of the means of production. Related with the differing conception of the main properties of the positions among which mobility is seen to occur, the two traditions also differ in their theoretical understanding of the mobility process, the methods used, and the main conclusions arrived at.

The Process of Status Attainment

Research pursued in the *status attainment* framework is often – even though not necessarily – embedded in a more general (liberal) theory of industrialism and shares with it assumptions about the impacts of industrialization on other aspects of social structure, notably social mobility. Industrialization is understood as a pervasive force that sooner or later affects all national societies across the globe. In this process, it is argued, the order of stratification in preindustrial societies in which *ascription* by family, kin, ethnic ties, gender, or status group affiliation determines the position of individuals in society, is increasingly replaced by a new order in which *achievement* based on individual abilities, qualifications, and work accomplishments play the decisive role in social selection (Blau and Duncan, 1967; Treiman, 1970). A fundamental trend toward rationalism and universalism is seen to unfold. To survive in markets, actors are forced by the technological sophistication of production processes and growing market competition to increasingly allocate individuals "to positions according to what they have shown they can do, rather than according to their social provenance" (Goldthorpe, 1996: 256). Notably formal educational qualifications are expected to increasingly determine the job level (successively) reached in bureaucratic work organizations. To enhance the development, states expand educational services, subsidize the costs of education, thus providing easier access to education for children in less-fortunate economic conditions. As industrialization progresses, social placement of individuals will then be conditioned less by their social origin, and intergenerational social mobility between the positions of parents and those of their children is expected to increase.

In this theoretical orientation, social mobility is understood as a process of successive status attainment by individuals, in which later attainment depends on earlier attainment. In line with the conception of the occupational structure as a graded hierarchy, this process is studied with variants of linear regression models (often path models or structural relations equations) to determine the extent to which the status or prestige level of a person's job at a given point in his or her career depends on earlier job achievements, educational qualifications, and directly or indirectly on parents' status. In the leading study – Blau and Duncan's (1967) *The American Occupational Structure* – education is identified as the main determinant of individuals' occupational careers and as the core link between

social origins and attained position. Parental education and occupational status also affect children's occupational status or incomes directly, but their effects are weaker than those of education. Parental education and status are mainly mediated through education. One far-reaching conclusion has been that under such conditions of status attainment – powered by individual achievement – the very basis for class solidarity and class action disappears. Extensions of the model have studied how other family conditions, personal abilities (intelligence, motivation), sociopsychological factors (parental encouragement and support, educational and occupational aspirations, peer contacts), or characteristics of schools intervene in these processes and contribute to generating them. In evidence from a number of societies at different levels of industrial development, Treiman and Yip's (1989) findings confirmed the expectation that status attainment becomes increasingly achievement based as industrialization unfolds.

The status attainment paradigm has come in for criticism on a number of counts. Its representation of the attainment process is individualistic and one-sidedly supply-driven, concentrating as it does on the way familial resources and individual human capital affect occupational and other outcomes. But the transformation of individual resources into outcomes depends on existing opportunities. The latter are constrained both by the distribution of available positions and by the competition of those contending for the same positions with similar or better resources. Further, the unidimensional representation of positions in terms of status or prestige obscures the way in which opportunities are bound up with structural transformations such as the shifts in forms of employment and between sectors, industries, and occupations. Groups like farmers, skilled industrial workers, small shopkeepers, and service workers hold positions that are heterogeneous in terms of their sociostructural location and affected in different ways by particular state policies and structural transformations. However, in terms of status or prestige, they all are similarly rated. In the hierarchical framework it thus appears difficult, if not impossible to trace mobility processes to their causal conditions.

Intergenerational Class Mobility and Social Fluidity

Proponents of the *class framework* have attempted to overcome these shortcomings by reorienting the study of mobility to analyze how individuals move between the social class positions existing within a class structure. The moves are represented in mobility matrices, which show the rates of transitions from given origin positions (from which moves start) to destination positions. In their elementary form, mobility matrices thus are bivariate frequency tables in which the cells contain the frequencies of transitions observed between origin and destination. Origin and destination can refer to different sets of positions. In the study of intragenerational mobility this is often the social class of first job and current job, but can also be any two successive positions in individuals' own working life. In the case of intergenerational mobility – which is of particular interest in the study of social mobility and to which we refer in the following – the classes compared are those of parents and those their children occupy in adult life. Several important strengths result from this reorientation. Compared to hierarchical ratings, the class characteristics allow the derivation of more realistic hypotheses concerning the greater or lesser likelihood of mobility between particular origins and destinations. Structural transformations and changing opportunity structures can be more specifically captured with class categories.

Of particular significance in this respect is the distinction between *absolute* and *relative* rates of mobility. *Absolute rates* refer to the observed absolute number of moves that take place in reality, and to proportions such as the percentage of children who have a different (percentage mobile) or the same (percentage immobile) class position as their parents. If the class categories are assumed to be ordered, distinctions are made between horizontal, upward, and downward mobility, meaning moves between classes at the same hierarchical level, moves from a lower to a higher and moves from a higher to a lower level, respectively. Other often used measures for absolute rates are *outflow* proportions (percentages of offspring of a given origin attaining particular destinations) or *inflow* proportions (percentages of members in a given destination recruited from the various origin classes).

Relative rates, in contrast, compare the relative chances the offspring of a given origin class – compared to those of another origin class – have to attain the various destination classes. These relative chances are assessed by so-called odds-ratios, which can be interpreted as measure of the advantages or disadvantages the progeny of one origin class compared to those of another origin class have in obtaining one destination class rather than another. The information contained in a mobility matrix can then be expressed in a set of such odds-ratios, which in turn can be analyzed by various log-linear modeling techniques (for early contributions see Goodman, 1970; Hauser, 1979; *see* Multivariate Analysis: Discrete Variables (Overview); Binary Response Models and Logistic Regression; 42062) Odds-ratios have the crucial property of being independent of the relative size of origin and destination classes (the so-called *marginal distributions* of the mobility matrix). As it is easier to obtain a position in larger (growing) rather than in smaller (shrinking) classes, the marginal distributions and the differences between the origin and destination distribution can be understood as capturing the structure of opportunities to reach different classes. The odds-ratios thus express the pattern of association between origin and destination independently of a given opportunity structure. They are therefore widely accepted to indicate the degree of *social fluidity* between the class positions of parents and their offspring, and in turn the degree of openness or rigidity of the class structure or the stratification system.

Relative rates thus are assumed to indicate the fundamental relativities existing in a mobility regime in the chances of people of different origin to reach the different destinations, or as Featherman et al. (1975) formulate: They indicate the genotypical pattern of the mobility regime in contrast to the phenotypical pattern revealed by the absolute rates. Even though absolute rates are more directly observed, theoretically they are conceived to be implied by the more fundamental conditions of social fluidity (measured by the relative rates) on the one side, and, on the other side, by the opportunity structures, which are assumed to be conditioned by macrostructural

economic and other developments and to influence the distributions of class positions available in particular times.

Given the differences in the conceptual understanding of absolute and relative rates of mobility, theoretical explanations for the two types differ, and findings are also likely to differ. As to relative rates, researchers emphasizing the hierarchical dimension have stressed the distances (in status or other considered dimensions) between positions as the mobility-generating principle (e.g., Hout and Hauser, 1992). The larger the vertical distance between positions, the less fluidity there will be between them. Sophisticated distance models have consistently shown considerable distance effects, but generally they cannot explain all details of the existing pattern. Researchers in the class framework have acknowledged the multidimensional nature of the resources that are available to the offspring of various class origins and that can be used for gaining access into classes of varying advantage and desirability. In a microtheoretical approach, Goldthorpe (2007) proposes an explanation in terms of – resource-constrained – rational action. Members of the various social classes pursue the same aims, giving priority to avoiding downward mobility and only in the second place seeking to achieve upward mobility. But in pursuing these same goals and priorities, the different amounts and kinds of resources and constraints typically available prompt the working and intermediate classes to use different strategies than the upper classes. In their comparative study *The Constant Flux*, Erikson and Goldthorpe (1992) developed a 'Core model' of social fluidity with four (im)mobility mechanisms in order to cover and analyze developments in a broad range of industrial societies up to the 1970s. They show that alongside the impacts of vertical '*hierarchy*' the fluidity pattern is markedly shaped by '*inheritance*' of parental class position (in all classes, but especially in the petty bourgeoisie, among farmers and in the service class), by the '*sector*' division between employment in agriculture and outside agriculture, and by special *affinities* expressing enhanced mobility among particular classes like the various nonmanual classes.

In a more recent paper, Jonsson et al. (2009) propose additional mechanisms for intergenerational class (im) mobility. Their 'microclass' approach sees typical class features (e.g., identity, social closure, collective action, and class outcomes) working at a detailed occupational level rather than through few analytically aggregated class categories. Accordingly, mechanisms of intergenerational reproduction mainly operate on a microclass level, e.g., through the transmission of occupation-specific human capital, occupation-specific cultures, tastes and networks, and fixed economic resources directly connected to parental occupations (e.g., business, farm). Their empirical analysis shows indeed an impressive effect of microclass inheritance, leaving additional (aggregated) class effects rather inconsequential, at least for men.

All in all, when assessed in terms of *relative rates*, class destinations in mature industrial societies continue to depend heavily on class origins. In England or France, for instance, the odds of a son born to a service class father obtaining a service class position rather than one in the unskilled working class is more than 20 times larger than the corresponding odds for an unskilled worker's son. Mobility is more likely to occur for intermediate classes while the likelihood of staying immobile in the parental class is larger in the most and least advantageous classes. Classes that require the ownership of material, financial capital, or land are 'inherited' to a clearly larger extent from the parental to the offspring generation than classes not requiring such assets.

Much research continues to address the question whether social fluidity differs between countries or changes over time. Erikson and Goldthorpe (1992) argue that the cumulative effect of different starting positions, resources, and strategies is so pertinent that it produces a high stability in the resulting outcomes, both across time and in different countries. They propose accepting, albeit only in a weak form, the hypothesis originally advanced by Featherman et al. (1975), that similar relative rates of social mobility exist in all industrial societies with a nuclear family system and a market economy. High degrees of cross-national commonality and constancy over time, however, are not to be equated with complete uniformity. Some limited, but nevertheless significant differences are found between societies and change is also found within some societies across time. As changes in time do not form a systematic trend (associated with industrial or some other macrosocietal development), Erikson and Goldthorpe favor Sorokin's (1927) assumption of 'trendless fluctuation.' Also, concerning differences between countries, there is hardly evidence for systematic explanations: The hypothesis of *exceptionally high* fluidity in the 'new' societies (United States, Australia, or Japan) cannot be confirmed. Nor does social fluidity systematically vary according to the political-economic order of countries: The former communist Eastern European societies show quite similar fluidity patterns and variations of them as in capitalist societies. Deviations from the core pattern appear to arise rather from historically contingent conditions resulting from a nation's particular economic, social, and political history or from specific institutional arrangements, for instance, in the educational system, in labor market segmentation, or in other institutions with an impact on specific elements of the fluidity pattern. For instance, the long-term equalizing policies by the social democratic governments in Sweden appear to have fostered fluidity in this country. The strong discriminatory measures pro- and contra particular classes in some phases of the communist period appear to have had corresponding effects in Hungary.

In a more recent study examining the development of social fluidity from the 1970s up to the 1990s in a number of mostly European societies, Breen (2004) and Breen and Luijkx (2004) largely confirm a high degree of commonality, but find somewhat more variation between countries and more change over time than Erikson and Goldthorpe (1992). In the 1990s, with the exception of Britain, all countries studied showed higher fluidity than in the 1970s, even though not all of these changes were statistically significant. Yet, countries did not become more similar in their fluidity pattern. In the 1990s, Germany, France, Ireland, and Italy had comparatively low levels of fluidity while Israel, the Netherlands, Sweden, Norway, Poland, and Hungary had a more fluid pattern of relative mobility. While Breen and Luijkx (2004) find no evidence that macrosociological characteristics such as the level of economic development or income inequality could explain the differences between countries and the change over time, they provide tentative hypotheses how characteristics of a country's

educational system (educational inequality and expansion and the strength of the linkage between educational qualifications and labor market outcomes) might influence the level of social fluidity.

Absolute rates differ more than relative rates between countries and across time. They depend on both the pattern of social fluidity and the opportunity structures. Related to economic and occupational change, mobility is induced as workers are 'forced' to leave areas of declining employment and gravitate to those which are expanding. Societies differ in their class composition and in the pace of change over time, and these differences in the opportunity structure induce differences in absolute rates between countries and across time even at a common or constant pattern of social fluidity.

In contrast to the relative rates, Breen and Luijkx (2004) find evidence that in more recent decades various aspects of absolute rates (total, upward, downward) converged between economically highly developed societies. This is mainly due to a growing similarity in the class structure of these societies: the agricultural classes are declining to a similarly low level while the service classes are increasing to a relatively similarly high level. With these developments absolute upward mobility slightly increased in most countries and – in the 1990s – was about twice as large as downward mobility. Depending on the kind and speed of changes in social fluidity and the transformation of the class structure, the probability of individuals moving between different classes will change. The absolute numbers of such moves determine the observable mobility experience of a population. They also strongly affect the composition of class membership by persons intergenerationally stable or recruited from other class origins. Even though they are likely to influence processes of class formation, these issues have been hardly studied so far.

Largely similar relative rates alongside varying absolute rates are also found, if different population subgroups are compared. Substantial differences between men and women, immigrants and natives, or between groups of different racial or ethnic affiliation can exist in absolute rates because the groups hold jobs in different segments of the labor market and their distribution among classes varies. But in terms of social fluidity they differ less. If they sometimes do, differences tend to be small. Inequalities in class distribution existing between men and women as a result of gender-segregated labor markets, for instance, are mostly not intensified by men and women being affected differently by their class origins. As a confirming corollary, it is found that in times when married women's labor market participation was low, social fluidity for daughters in the marriage markets has been rather similar to the relative mobility prospects of their brothers in the labor market. With respect to gender, another highly debated issue concerns the proper unit of stratification, class and mobility analysis. Is it (always) women's or men's own position in the labor market that determines their social status or class affiliation, or is it rather the common position of the family unit? As women's labor force participation has increased and has become more continuous, the most convincing answer is to study the issues separately to analyze men's and women's labor market careers and social mobility separately, likewise their household division of labor and resource utilization, but also the common position they may share.

In the figures on mobility or immobility between social origin and eventual destination, whether viewed in absolute or relative terms, the process of intergenerational social reproduction is only reflected in its global outcomes. It results from various intervening processes, notably educational attainment, transition from education to work, and mobility between successive jobs in working life within and between firms. These processes have to be – and are – studied on their own right (*see* Life Course: Sociological Aspects). Of these, the role of education has been scrutinized most intensively. The fact that education is a prerequisite for access to professional and managerial jobs makes it an important channel for upward social mobility, but evidently one which the more advantaged families also make use of to secure favorable positions for the next generation. Further, while education is found to be the main carrier responsible for the hierarchical element in the fluidity pattern, this is much less true – in some cases not true at all – in the case of other elements or mechanisms that produce immobility (Ishida et al., 1995). Transfer of capital or business, provision of social contacts, or inculcation of the proper social skills and manners are some of the means prosperous families have to back their children outside school and which they can rely on to compensate for possible failure in education. Studies pursued in the class framework so far have not found any evidence consistently supporting expectations of a *general* trend toward increased education-based or 'credentialist' social selection in late-industrial or postindustrial societies, at least not in the sense of education consistently becoming a stronger predictor of social destination. Rather, in many countries the predictive power of education has tended to weaken, especially when the proportions of highly educated people has exceeded the demand for such qualifications on the labor market. On the other side, over time educational attainment became less dependent on social origin in several countries (see Breen et al., 2009, contesting the earlier conclusion of persistent educational inequality by Shavit and Blossfeld, 1993). Declining educational inequality can contribute to increasing social fluidity. Yet such changes appear to be limited in extent and tend to affect cohorts in education at a particular time. Accordingly, much of the change in social fluidity of a population can be attributed to the replacement of older, more immobile cohorts with younger, more mobile cohorts (Breen and Jonsson, 2007). But the effects of declining educational inequality on social mobility tend to be small, and to affect social mobility in the population at large it will take long times.

Alternative Approaches to Social Mobility

Class- or status-based approaches are often challenged for their choice of unit of analysis (individuals vs family or household) and their rootedness in occupational characteristics, leaving long-term unemployed or inactive persons out of the analysis. Thus, some researchers, economists in particular, favor measures of (household) income or wealth as an underlying hierarchy in society. They split income or wealth distributions of origin and destination positions into segments (percentiles) and calculate correlations or elasticities between origin and destination segments. The empirical

robustness of these approaches has often been weak due to the lack of appropriate data (small samples, imprecise measures of long-run income estimated from short-run fluctuating data). With improved data bases and clarification in concepts and corresponding statistical measures, recent research has made substantial progress (for a review see Björklund and Jäntti, 2009). Based on large administrative data sets from tax records, Chetty et al. (2014) study whether in the United States the increasing inequality in income distribution has been connected – as some earlier research claims – with increasing intergenerational persistence of incomes. Findings differ depending on the aspect addressed. Similar to the sociologists' distinction between relative and absolute mobility, Chetty et al. (2014) distinguish the association between parent and child percentile rank in the income distribution on the one side, and the inequality in the marginal distribution of incomes in the parent and child generation on the other side. For children born between 1971 and 1992, the association between the (relative) income ranks has not changed in spite of growing inequality in the marginal distribution. Yet due to the latter, the inequality in (absolute) incomes of children raised in a family in the bottom income quintile compared to those in the top quintile has widened substantially – since "the rungs of the income ladder have grown further apart" Chetty et al. (2014). Yet, also because of an increasing dispersion, the chances of a child from a low-income family (i.e., low percentile) to gain an income beyond a high threshold of, e.g., $100 000 have *improved*. As for the US cohorts born between the 1950s and the 1970s, Hertz (2007) and Lee and Solon (2009) find intergenerational income association similar to those observed for the more recent cohorts by Chetty et al. (2014), stability in the association appears to have prevailed in the United States over much of the post-World War II period. According to Chetty et al. (2014), this stability for the United States at large appears to exist hand in hand with stable differences in the size of the association in different regions of the United States. From international comparisons findings accumulate showing differences between countries: The United States is among the countries with high intergenerational income association while the link between parents and children's income position is considerably lower e.g., in several of the Scandinavian countries.

Sibling correlations are an alternative approach to assess social mobility without relying on the classical origin-destination pattern in terms of class or income positions. Sibling correlations examine correlations of various economic and noneconomic outcomes (like wage, income, education, or physical attributes) among two or more children of a family and draw conclusions on the effect of the origin family on these very outcomes. Estimating these effects is a challenging task, given that high correlations among siblings may have various causes (same family of origin, same neighborhood, same school, etc.).

Few studies in social mobility research, usually very limited in scope, turn their focus to the causal study of specific mobility mechanisms. Systematic interventions studies, especially in the educational context, examine potential long-term upward mobility pathways, drawing on experiences from the classical Perry Preschool Project (Heckman et al., 2009). Other studies concentrate on, for example, discriminating behavior of employers in the (class) position attainment process by using experiments with mock applications (Jackson, 2009). Thus, much work needs to be done, when it comes to causal explanations of what can be said in descriptive accounts.

Model Selection and Model Averaging

Gerda Claeskens, ORStat and Leuven Statistics Research Center, KU Leuven, Leuven, Belgium

Abstract

Model selection methods provide a way to select one model among a set of models in a statistically valid way. Such methods include tools for variable selection in regression models. Asymptotic properties such as consistency and efficiency, the specific use of the model, or properties regarding minimization of a certain risk function such as the expected prediction error, may help to decide which method to choose. Model selection is a special case of model averaging where the estimators obtained from different models are combined in a weighted average. Model averaging avoids the selection of one model. The choice of the weights may be determined by a model selection method or may come from a priori knowledge in a Bayesian framework.

Introduction

Statistical models may not coincide with the true, physical model that has generated the data. This may be because the true model is too complicated from the mathematical or computational points of view, or simply because the precise model is unknown. Even if the precise model is known and computationally feasible, a simplification could be preferable. As an illustration, consider two quantities x and y that are related by a law $y = \beta_0 + \beta_1 x + \beta_2 x^2$, and suppose we observe x_i along with $Y_i = \beta_0 + \beta_1 x_i + \beta_2 x_i^2 + \varepsilon_i$, with independent zero mean normal errors ε_i. If we are interested in the value of y corresponding to $x = x_0$, then least squares regression estimators for the values of β_i lead to an unbiased estimator for y. For small values of β_2, however, it might be interesting to adopt a model without the quadratic term. The bias introduced by dropping this variable from the model might be compensated by a reduction in variance. The statistical bias-variance tradeoff suggests in such case that a simpler, but incorrect model outperforms the true model. In addition, the simpler model may have an easier interpretation in the practical context.

The best performing statistical model is also dependent on the parameter to be estimated. In the example above, the model without the quadratic term would obviously fail if we were interested in the value of β_2. Not all models have the same performance. Some models may be good for prediction purposes, other models concentrate on particular features of the data.

These considerations leave the researcher the difficult task to select an appropriate model. Alternatively, instead of selecting one model and further ignoring the other models, estimates or predictions arisen from different plausible models may be combined to lead to model-averaged estimates or predictions.

Model selection methods are developed to select models in a statistically valid way. Model averaging is a wider concept that allows to combine estimators in a weighted average of single model estimators and that offers the possibility to take the uncertainty of the model choice into account when working further with a selected model.

Information Criteria

Model selection has been well studied in regression models for the problem of variable selection. Some of these criteria, such as R^2 and Mallows' C_p are only valid in multiple linear models, other criteria are valid to select more general models (e.g., likelihood-based) and to various estimation methods (e.g., maximum likelihood estimation, nonparametric estimation). Several of such methods for model choice are listed below. Numerous books on this topic have been published, including those by Linhart and Zucchini (1986) and Miller (2002), with a large focus on regression models, the edited monograph by Lahiri (2001), Burnham and Anderson (2002), with an emphasis on the Akaike information criterion (AIC), and that by Claeskens and Hjort (2008).

The Value of R^2 in Linear Regression Models

The question of which variables to include in a linear regression model is a classical example of model choice. Consider a linear model of the form $Y_i = \beta_0 + \beta_1 x_{1,i} + \ldots + \beta_p x_{p,i} + \varepsilon_i$ for $i = 1, \ldots, n$, where often a normal distribution is assumed for the variables $\varepsilon_1, \ldots, \varepsilon_n$ with mean zero and variance σ^2. A summary value of the regression model is the R^2 value, the value of multiple determination, defined as the proportion of the variation of the response that is explained by the regression model. More precisely, $R^2 = \mathrm{SSR}(\widehat{\beta})/\mathrm{SST}$ with $\mathrm{SST} = \sum_{i=1}^n (Y_i - \overline{Y})^2$ with $\overline{Y} = n^{-1}\sum_{i=1}^n Y_i$ and $\mathrm{SSR}(\widehat{\beta}) = \sum_{i=1}^n (\widehat{Y}_i - \overline{Y})^2$ with $\widehat{Y}_i = \widehat{\beta}_0 + \widehat{\beta}_1 x_{1,i} + \ldots + \widehat{\beta}_p x_{p,i}$, the prediction formed by inserting the least squares estimators for the unknown parameters. We also define $\mathrm{SSE}(\widehat{\beta}) = \mathrm{SST} - \mathrm{SSR}(\widehat{\beta})$. The larger the value of R^2, the better the model. Let the model with p regression coefficients be the full model, i.e., the largest model one is willing to consider. An all subsets search fits all possible submodels of this full model by leaving out some (or all) of the covariates. The simplest model includes a constant only: $Y_i = \beta_0 + \varepsilon_i$. For each such submodel the corresponding R^2 value can be computed and the submodels may be ranked according to their R^2 value. Since including more variables in a model cannot decrease the R^2 value, this is not satisfactory to select

a good model. Better is the adjusted R^2 value where the degrees of freedom, the number of parameters in the fitted model, is taken into account, $R^2_{\text{adjusted}} = 1 - \frac{\text{SSE}(\widehat{\beta})/(n-p-1)}{\text{SST}/(n-1)}$. The model selection strategy is then to select a model with a small number of variables for which the corresponding adjusted R^2 value is large.

Mallows' C_p

Minimizing the mean squared prediction error $\text{PE}(\beta) = E[\sum_{i=1}^{n}\{\widehat{Y}_i - E(Y_i)\}^2]$ in multiple regression models is the idea behind the C_p construction of Mallows (1973). The sample version is defined by $C_p = \text{SSE}(\widehat{\beta})/\widehat{\sigma}^2 + 2p - n$, where $\widehat{\sigma} = \text{SSE}(\widehat{\beta}_{\text{full}})/(n - \text{q} - 1)$ with q the number of parameters in the full model and $\widehat{\beta}_{\text{full}}$ the full model least squares estimator of β. The statistic C_p is constructed as an estimator of the scaled squared prediction error $\text{PE}(\beta)/\sigma^2$. Models with a large bias tend to have C_p values that are larger than p. The best model according to this method is that model with the smallest value of C_p, which is often identified via a graphical representation of the values of C_p versus p.

Akaike's Information Criterion

The information theoretic approach of Akaike (1973) tries to find a model that comes close in Kullback–Leibler discrepancy to the true model. This method assumes the existence of a true model, but does not need to have knowledge about that model for the actual calculation of the criterion value.

Let $f(y; \theta)$ denote the modeled density, possibly depending on unknown parameter values θ, and let g be the true density, then the Kullback–Leibler discrepancy between the model and the true densities is defined by $\text{KL}[f(\cdot;\theta), g] = \int \log[g(y)/f(y;\theta)]g(y)\text{d}y$. When $f = g$, the Kullback–Leibler discrepancy is equal to zero, for all other densities f it holds that $\text{KL}(f, g) \geq 0$. A good model has a small value of $\text{KL}(f, g)$.

For independent and identically distributed data $Y_1, \ldots, Y_n$, the estimator $\widehat{\theta}$ that maximizes the log likelihood $\sum_{i=1}^{n}\log f(Y_i;\theta)$ converges, under some conditions (see, e.g., White, 1994), almost surely to the value θ_0 that minimizes $\text{KL}[f(\cdot;\theta), g]$.

The AIC results from estimating the expected value of $\text{KL}[f(\cdot;\widehat{\theta}), g]$. This leads to $\text{AIC} = -2\sum_{i=1}^{n}\log f(Y_i;\widehat{\theta}) + 2p$, with p the length of the vector θ. For regression models where covariate vectors x_i are observed together with a response value Y_i, for $i = 1, \ldots, n$, AIC similarly is defined as $\text{AIC} = -2\sum_{i=1}^{n}\log f(Y_i; x_i; \widehat{\theta}) + 2p$.

The general strategy in model selection via AIC is to compute for each model under consideration the value of the corresponding AIC for the given dataset and to rank the models according to their AIC value. The model with the smallest AIC is considered the best model.

The AIC values may be compared for non-nested models and do not need any knowledge about the true model. This method is applicable to more general model selection and is not restricted to variable selection within a model class. Consider, for example, the choice between an exponential density function and a Weibull density that has one additional parameter. The AIC values of both models may be computed on a given dataset and the smallest AIC value determines for that dataset which model is preferred in the sense of having the smallest estimated expected Kullback–Leibler discrepancy.

The concept of using AIC for variable selection has been extended in various ways toward various forms of model misspecification, robustness against outliers, estimation using other methods than maximum likelihood, corrections for small sample sizes, mixed models containing both random and fixed effects, missing data, etc. See, for example, Claeskens and Hjort (2008) and Burnham and Anderson (2002).

The Schwarz Bayesian Information Criterion

The Bayesian Information Criterion (BIC) has been proposed by Schwarz (1978) and Akaike (1977, 1978). One reason for its development was to have a selection method with different asymptotic properties than the AIC, see further in Section Asymptotic Properties of Model Selection Methods.

While the name of the criterion refers to Bayesian methods, its computation does not require any knowledge of Bayesian procedures. In fact, the formula of the BIC differs only from that of the AIC in the last term. For the situation of a model for independent and identically distributed data, $\text{BIC} = -2\sum_{i=1}^{n}\log f(Y_i;\widehat{\theta}) + p\log(n)$,with p the length of the vector θ and log the natural logarithm with base exp(1). For regression models BIC is similarly defined as $\text{BIC} = -2\sum_{i=1}^{n}\log f(Y_i; x_i, \widehat{\theta}) + p\log(n)$. The BIC has been extended toward allowing other types of models and estimation methods.

The definition for BIC originates as an approximation of the posterior probability of a model given the data (see, e.g., Claeskens and Hjort, 2008: Section 3.2.2), the priors do not appear in the BIC formula. A Laplace approximation is applied to the marginal likelihood for the model where the parameters that are present in the model are integrated over their parameter space with respect to their prior density. Only the most important terms in this approximation are kept, leading to the BIC. The absence of prior information in the BIC makes this perhaps less attractive from a Bayesian point of view. Other Bayesian approaches have been developed, such as working with Bayes factors and the use of the deviance information criterion (Spiegelhalter et al., 2002). Minimum description length also may include aspects of Bayesian modeling for model choice (Rissanen, 1996; Grünwald, 2007) (*see* Bayesian Model).

The Focused Information Criterion

The idea behind the focused information criterion (FIC, Claeskens and Hjort, 2003) is that a good model should lead to a small mean squared error for the focus, that is, a parameter that one wishes to estimate using the model. The mean squared error of an estimator is a sum of the squared bias and the variance of that estimator. The value of FIC for a given focus μ and a given model is an estimator for the mean squared error of $\widehat{\mu}$ computed using that model. Different models may give rise to different estimators of μ, hence to

different mean squared errors and to different values of the FIC. The model with the smallest value of FIC is considered the best model.

Consider as an example a multiple regression model where we wish to estimate $\mu = \beta_0 + \beta_1 x_1 + \cdots + \beta_p x_p = \beta^t x$. Allowing different submodels to be fit, leads to different estimators $\widehat{\mu}_s = \widehat{\beta}_s^t x_s$ where the subscript $_S$ denotes working with a subset of the variables only. For example, the narrow model estimator $\hat{\mu}_\emptyset = \hat{\beta}_0$, and the estimator in the model only including variables x_2 and x_3 is $\widehat{\mu}_{\{2,3\}} = \widehat{\beta}_0 + \widehat{\beta}_2 x_2 + \widehat{\beta}_3 x_3$. We wish to select that submodel for which μ is estimated with the smallest mean squared error.

A good model for estimation of μ should correspond to an estimator that has a small or no bias and at the same time a small variance. This leads to a bias–variance tradeoff since typically models with a large number of parameters will tend to have a small bias, but a large variance since many parameters need to be estimated. On the other hand, models with only a small number of parameters might have a small variance but tend to have larger bias values.

The calculation of the mean squared error requires the knowledge of a true model. Therefore, the derivation of the FIC assumes a local misspecification setting where the true model takes the form of the full model but with true parameter values of the form $\theta_0 + \delta/\sqrt{n}$ with n the sample size. This allows the calculation and estimation of the mean squared error for the estimators.

One important consequence of directing the model search toward performing well for the specified focus is that different focus quantities might lead to different selected models. In the above multiple regression example, this might mean that specifying another vector $\tilde{x}$, perhaps at the boundary of the covariate space, while the former x could have located near the center, might lead to selecting a different model. Specifying the error variance σ^2 as a focus could also require a different model for best estimation in mean squared error sense. This is in contrast with other information criteria that select one model for all purposes.

The use of the FIC has been extended toward non- and semiparametric estimation, survival data analysis, quantile regression, and time series models to name just a few areas.

Cross-Validation and Generalized Cross-Validation

The method of cross-validation splits the dataset (usually multiple times) into a so-called training set and a validation set. These two sets do not need to have the same size. Typically a model is fit using the training set. The validation set is then used to compute the value of an expected loss function, the risk function, using that fitted model. When multiple splits of the dataset are used, the resulting risk functions are averaged (or summed), which is named the cross-validation value. When this process is repeated for different models, the model with the smallest such cross-validation value is considered the best one.

In multiple regression models, leave-one-out cross-validation applied to the prediction sum of squares leads to the PRESS statistic (Allen, 1974). One observation vector, say the ith one $(y_i, x_{1,i}, \ldots, x_{p,i})$, is left out of the dataset. The remaining data values are used to fit a multiple regression model leading to estimated coefficients $\widehat{\beta}_j^{[-i]} (j = 0, 1, \ldots, p)$ that are used to predict the value Y_i via $\widehat{Y}_i^{[-i]} = \widehat{\beta}_0^{[-i]} + \widehat{\beta}_1^{[-i]} x_{1,i} + \cdots + \widehat{\beta}_p^{[-i]} x_{p,i}$. This prediction is considered more honest than the least squares prediction using all of the data values since here the prediction is performed for a value that is not already used for estimation of the regression coefficients. One then considers PRESS $= \sum_{i=1}^n (Y_i - \widehat{Y}_i^{[-i]})^2$. Since the leave-one-out predictions depend on the variables that are in the model, submodels may be ranked according to their value of PRESS. The model with the smallest value of PRESS is considered the best one.

For large datasets typically the dataset is divided into k parts (k is usually between 3 and 10). One part is the validation set, the other $k-1$ parts are together the training set. This approach named k-fold cross-validation is less time consuming than leave-one-out methods. For an overview on cross-validation, see Arlot and Celisse (2010).

As the training and validation procedure of cross-validation can be time consuming, the idea of cross-validation can be formalized and then generalized into the much simpler expression of generalized cross-validation (GCV). GCV is a function of the estimated parameter $\widehat{\beta}$ within a model under consideration. This function can be minimized over all possible models, with their corresponding estimators. $\mathrm{GCV}(\widehat{\beta}) = \mathrm{SSE}(\widehat{\beta})/(1 - \nu/n)^2$, where ν is a generalized concept of degrees of freedom (Ye, 1998), which depends on the model under consideration as well as on the estimation within that model. The expression of GCV can be analyzed to be closely related to the formula of Mallows' C_p.

Asymptotic Properties of Model Selection Methods

One of the favorable properties that a model selection method may have is efficiency. In the setting of a multiple regression model, by efficiency is understood that, conditional on the selected model, the ratio of the expected squared prediction error for predictions using this model for the sample values, $\sum_{i=1}^n E[(\widehat{Y}_i - Y_i)^2]$ and of the best possible such expected squared prediction error among the considered models, say this occurs for model S^* with predictions $\widehat{Y}_{i,s*}$, $\sum_{i=1}^n E[(\widehat{Y}_{i,s*} - Y_i)^2]$, converges in probability to one when the sample size grows toward infinity. It has been shown that AIC, the small sample corrected version of AIC and Mallows' C_p are among the efficient selection criteria (Hurvich and Tsai, 1995; Lee and Karagrigoriou, 2001). Yang (2005) has obtained the minimax rate optimality of information criteria of the AIC-type. The BIC and Bayesian model averaging are shown to be not efficient and not minimax rate optimal.

Consistency of the selection is another asymptotic property that some criteria may possess. Sin and White (1996) study consistency for a general class of information criteria. If there is only one model in the collection of considered models that comes closest to the true model in Kullback–Leibler discrepancy, then a weakly consistent criterion shall with probability one select this model, when the sample size tends to infinity. Weak consistency requires weak

assumptions and is satisfied by a large number of criteria for which the penalty term is of the order $o_P(n)$, including both AIC and BIC.

Consistency is a stronger property. This involves selecting the true model when it is one of the considered models, and selecting a parsimonious model, that is a model with a small number of parameters, when there are two or more models that are otherwise close in Kullback–Leibler distance, or for which the log-likelihood ratio statistic is bounded in probability. For precise conditions, refer to Sin and White (1996). The BIC and the criterion of Hannan and Quinn (1979) are shown to be both consistent and strongly consistent under some conditions. The latter property concerns almost sure convergence, while consistency involves convergence in probability. The criteria AIC and Mallows' C_p are among the nonconsistent criteria.

Having efficiency and consistency properties at the same time is not possible (Yang, 2005). This issue also holds when consistent choices for the weights in model averaging are used, in particular Bayesian model averaging is not minimax rate optimal (Yang, 2005).

Pretesting and Conditional Inference

Once a model is selected from a collection of available models, proper inference should take the uncertainty involved with the selection into account as indeed the selected model is random. Too often, however, this source of uncertainty is ignored. The same ignorance arises with pretesting when only coefficients that are significantly different from zero are included in a model. Danilov and Magnus (2004) explain that model selection and estimation should be studied simultaneously. Working conditional on the selected model leads to too optimistic statements in the sense that, for example, confidence intervals are too narrow (Hjort and Claeskens, 2003; Leeb and Pötscher, 2005).

The randomness involved with model selection may be studied by writing an estimator of a model quantity (this may be a parameter in the model, or another focus such as a prediction at a certain location) in a selected model as a weighted average of the estimators in all considered models. Since only one model is selected, this implies that all but one weight are zero. The nonzero weight is set equal to one. The choice of which weight equals one depends on the data, implying randomness of the weights.

While the asymptotic distribution of the estimator in each model might be normal, the randomness of the weights causes the asymptotic distribution of the randomly weighted estimators to be non-normal in most cases. Proper inference on estimators-post-selection is difficult (Hjort and Claeskens, 2003; Leeb and Pötscher, 2008).

Model Averaging

While post-selection estimators use zero/one weights, allowing the weights assigned to estimators in different models to take on values other than zero or one leads to model averaging estimators which take the form $\widehat{\mu}_{\text{weighted}} = \sum_{S\in \mathbf{S}} w_s \widehat{\mu}_s$, with S being a collection of models that is used and w_S being the weight given to the estimator $\widehat{\mu}_s$ in the model identified by S. Often it is imposed that the weights sum to one and take values between 0 and 1.

Since information criteria provide a ranking of models according to their value of the criterion, values of information criteria such as Mallows' C_p, AIC, BIC, and FIC have been used to construct weights for model averaging (see, e.g., Hansen, 2007; Burnham and Anderson, 2002). Estimators $\widehat{\mu}_s$, $S \in \mathbf{S}$ in the considered models receive a weight proportional to the value of the corresponding model selection criterion, the better, the higher ranked the model according to that selection method, the larger the weight. Such 'smooth' weights as opposed to zero or one values for model selection avoid the problem that slight changes in the data would cause another model to be selected (thus switching between weight zero and weight one for the involved models). Another advantage is that all estimators from the considered models are used. Such weighted estimators are referred to as frequentist model averaging estimators (Hjort and Claeskens, 2003).

Prior information on the models leads to another choice of weights that is used in Bayesian model averaging (see, e.g., Hoeting et al., 1999) (*see* Bayesian Statistics). Once the prior probabilities are specified for each of the models in the considered model collection and for the parameters in those models, a challenge with Bayesian model averaging is in the computation of the posterior probabilities that are used in the construction of the weights.

Bayesian model averaging is much applauded since once values can be obtained from the posterior distribution of the weighted estimator $\widehat{\mu}_{\text{weighted}}$, the resulting inference takes the weight specification into account. This is different in frequentist model averaging where the calculation of the weighted estimator is relatively easy though its distribution is difficult to study (Hjort and Claeskens, 2003).

High-Dimensional Variable Selection

Best *n*-term Selection

In high-dimensional problems, the number of observations n is smaller than the number of parameters in the full model, from which it follows that not all parameters can even be estimated within that model. A typical solution for this underdetermination is to impose sparsity, i.e., to propose an estimator in which the vast majority of the variables are set to zero. Sparsity can be imposed by optimization of the sum of squared residuals with a regularization term, as in $\text{SSE}(\beta) + \lambda\|\beta\|_q$. With $\beta = (\beta_1, \ldots, \beta_p)$, the norm $\|\beta\|_q = \{\sum_{j=1}^{p} \beta_j^q\}^{1/q}$ is chosen to promote sparsity. The cases of ℓ_q-norms with $q = 0$ and $q = 1$ are discussed in more detail later. The regularization parameter λ can be seen as a Lagrange multiplier for the constrained optimization problem to find the minimum of $\text{SSE}(\beta)$ for which $\|\beta\|_q \leq C$, for a constant C which is determined by λ and vice versa.

Taking $q = 0$, the regularization term is a pseudonorm, simply counting the size of the model $\|\beta\|_0 = \#\{i; \beta_i \neq 0\}$. The estimator that minimizes the ℓ_0 regularized SSE is the least squares estimator within a submodel. In order to find the

global optimum of the ℓ_0 regularized problem, one needs to compare the SSE-values of all submodels, which is a problem of combinatorial complexity.

As an alternative, the ℓ_0 regularization can be replaced by an ℓ_1 regularization. The constraints are then linear instead of combinatorial, thereby reducing the optimization to a quadratic programming problem, which is a convex optimization problem. The problem is known as 'least absolute shrinkage and selection operator' or lasso (Tibshirani, 1996) or as basis pursuit (Chen et al., 1998). Algorithms solving the problem include direct solvers such as least angle regression (Efron et al., 2004), as well as iterative methods, such as iterative soft-thresholding (Daubechies et al., 2004) or gradient projection (Figueiredo et al., 2007). While dramatically reducing the computational cost, the outcome is still a sparse estimator for β. It has been found that if the regularization parameter is not too large and if the nonzeros in the true model are sufficiently prominent, then ℓ_1 constrained optimization is variable selection consistent (Meinshausen and Bühlmann, 2006; Wainwright, 2009; Tropp, 2006; Zhao and Yu, 2006). It has also been found that, for given λ, ℓ_1 constraints find approximately the same model as ℓ_0 constraints (Donoho, 2006).

Shrinkage

There is, however, a major difference between ℓ_0 and ℓ_1 constrained least squares. Whereas ℓ_0 constraints lead to least squares estimators within the selected model, ℓ_1 constraints lead to a shrinkage estimator within the selected model. More precisely, let I indicate the set of selected indices from β, and X_I the submatrix of X formed by selecting from X the columns indicated by I, then the Karush–Kuhn–Tucker conditions for the constrained optimization problem are

$$\left(X_I^t X_I\right)\widehat{\beta} = \mathrm{ST}_\lambda\left(X_I^t Y\right)$$

where ST_λ is the soft-threshold function with threshold λ, which is defined by $\mathrm{ST}_\lambda(x) = 0$ if $|x| < \lambda$, $\mathrm{ST}_\lambda(x) = x + \lambda$ if $x \leq \lambda$, and $\mathrm{ST}_\lambda(x) = x - \lambda$ if $x \geq \lambda$.

The shrinkage in the soft-threshold function has several benefits. It reduces the influence of false positives in the selection. This may result in better prediction errors, known as Stein's phenomenon (Stein, 1956). Shrinkage comes out from a computationally more attractive problem, but it is also mathematically more tractable, especially when optimizing over λ.

The Sparse Variable Selection Problem

The regularization parameter λ controls the balance between residual and sparsity norms. It thus determines the size of the selected model. Variable selection is done by choosing the appropriate value of λ. As ℓ_0 and ℓ_1 constraints lead to different estimators within the selected model, the best model for estimation without shrinkage does not coincide with the best model for estimation with shrinkage. Finding the best model for estimation without shrinkage is more delicate, as the prediction error for a misspecified λ rapidly increases (Jansen, 2014). As shrinkage reduces the effect of false positives, the ℓ_1 problem is too tolerant for false positives, leading to considerably overestimating the size of the true model (Jansen, 2014).

Abstract

Tests of the validity of probability models can be based on classical chi-squared statistics for discrete random variables. For continuous random variables, chi-squared-based methods are available as well as procedures using order statistics and log-likelihood ratio tests, among others. Classical approaches to model selection are also based on model-fit tests. A related approach is based on tests between hypotheses that correspond to the different families of models. Other approaches are the Bayesian approach, the discrepancy-based method to select models with the goal to minimize the expected value of a given discrepancy criterion, and selection based on the minimum description length principle.

One of the main tasks of applied statisticians is to construct probability models for observations. This means representing the observations in terms of random variables and parametric families of distributions. To fit a model is to provide an estimate of the probability distribution of these random variables. Goodness-of-fit statistics measure the discrepancy of the observed from the estimated distribution. Goodness-of-fit tests are used to decide whether these discrepancies are significant under the null hypothesis that the model holds. Model selection is the process of selecting one from different families of competing models. Model fit and model selection are closely related.

This article reviews procedures for assessing model fit and techniques for selecting models. Classical chi-squared-based approaches to model fit provide goodness-of-fit tests for discrete random variables that take only a finite number of different values. For continuous random variables, chi-squared-based methods are available, as well as procedures using order statistics and log-likelihood ratio tests, among others. Methods of Bayesian model checks and model criticism are also considered.

The focus here is on goodness-of-fit measures with a reference distribution that is known at least for large samples in classical goodness-of-fit approaches. There are many indices, measures, and graphical methods designed to capture aspects of model fit in a descriptive manner in different fields. For example, in structural equation modeling, there is a multitude of indices that are often considered in assessing a model's fit based on heuristical recommendations for appropriate cut-off values. Among these are the adjusted goodness-of-fit index, the standardized root mean square residual, the nonnormed fit index, the normed fit index, the expected cross-validation index, the comparative fit index, and others (Schermelleh-Engel et al., 2003). Furthermore, we focus on those approaches for assessing goodness of fit that are general-purpose methods applicable to large classes of families of distributions rather than being tailored to a specific family such as the family of normal distributions.

Classical approaches to model selection build on goodness-of-fit tests, in that they select the simplest model that fits the data. A related approach is based on tests between hypotheses that correspond to the different families of models. Other approaches considered include the Bayesian approach, within which the Bayesian information criterion (BIC) is motivated. In the discrepancy-based method, models are selected with the goal to minimize the expected value of a given discrepancy criterion, thereby typically striking a balance between parsimony and goodness of fit. Akaike's information criterion (AIC) is an example. An information-theoretic approach to model selection is based on the minimum description length principle, leading to the normalized maximum likelihood (NML) index for model selection and a Fisher information approximation to it.

Models

In a probability model, observed values x are assumed to be realizations of random variables X with probability distribution Q that is an element of a parameterized family of probability distributions $M = \{P_\theta, \theta \in \Theta\}$, where θ may be a vector with several components and Θ, the parameter space, is the set of values that can be taken by θ. The model is the family of distributions. A model is said to be nested in another model if its family of distributions is a subset of that of the second model.

Goodness of Fit

Assessing goodness of fit means the statistical testing of models with data. Based on a random sample $x_1, \ldots, x_n$ realizing random variables $X_1, \ldots, X_n$ with distribution Q, it is thus required to test the null hypothesis:

$$H_0 : Q \in M$$

Most goodness-of-fit tests are parameter-free, that is, the distribution of the test does not depend upon θ, at least asymptotically, that is, as the sample size increases.

Goodness-of-Fit Testing for Discrete Random Variables

Many traditional goodness-of-fit statistics were originally developed for discrete random variables. Discrete random variables take only a finite (or at most countably infinite) number of values. They underlie statistical models of categorical data (Agresti, 1990). The probability distribution Q of a discrete random variable X can be specified by its probability function $q(x) = Q(\{x\})$, which assigns the probability of the set

$\{x\}$ to x. Likewise, the probability distribution of P_θ is specified by the probability function $f(x|\theta) = P_\theta(\{x\})$.

Let N_x be the number of X_i with $X_i = x$, and let n_x be a realization of the random variable N_x. Goodness-of-fit tests are based on asymptotically efficient estimators $\hat{\theta}_n$ of θ such as the maximum likelihood estimator under H_0. The two most widely used tests are given by the log-likelihood ratio statistic, where log is the natural logarithm:

$$G^2 = -2\sum_x n_x[\log nf(x|\hat{\theta}) - \log n_x] \qquad [1]$$

and Pearson's chi-squared statistic:

$$X^2 = \sum_x (n_x - nf(x|\hat{\theta}))^2/(nf(x|\hat{\theta})) \qquad [2]$$

where n is the total number of observations in the sample.

Under H_0 and given suitable regularity conditions, each of the above statistics is asymptotically distributed as χ^2 with degrees of freedom given by the number of different data categories x that can occur in principle minus the number of independent parameters minus one. In practice, it may be necessary to aggregate data from several categories, forming new, composite categories from categories x for which $nf(x|\hat{\theta})$ is small for the asymptotic approximation to be adequate. Different rules of thumbs have been proposed for what constitutes an adequate cell size. Although the statistics of eqns [1] and [2] are most well known, there are many others (Read and Cressie, 1988).

Goodness-of-Fit Testing for Continuous Random Variables

Goodness-of-fit tests for models of continuous random variables can be based on those for the discrete case and on the order statistics. Apart from general-purpose methods, special tests have been developed to test for exponential and normal families of distributions among others (D'Agostino and Stephens, 1986).

The goodness-of-fit test for models of discrete random variables can be applied to the continuous case by grouping the values of the random variables by means of a finite number of intervals I_x, $x = 1, \ldots, k$. For this purpose, compute $p(x|\theta) = P_\theta(I_x)$; n_x, the number of observations falling into I_x, and, finally, the above test statistics on the basis of these grouped data and probability distributions. Estimation of θ should be based on the grouped data rather than on the original likelihood. Note that a subjective element enters the test through the choice of the intervals I_x. A rational choice is to define I_x so that $P_{\hat{\theta}}(I_x) = 1/k$, $x = 1, \ldots, k$. Although this makes the intervals dependent upon the random sample via $\hat{\theta}$, the asymptotic χ^2-distribution of the above test statistics is not compromised (Moore and Spruill, 1975). When the maximum likelihood estimates based on the ungrouped data are available, generalized chi-squared statistics such as the Rao–Robson statistic (D'Agostino and Stephens, 1986) provide more powerful goodness-of-fit tests and should be preferred.

Given continuous real-valued random variables $X_1, \ldots, X_n$, the so-called order statistics $X'_1, \ldots, X'_n$ correspond to the values of the random variables ordered from the smallest to the largest and thus, $X'_1 < \ldots < X'_n$ (with probability one). Let $0 = \lambda_0 < \lambda_1 < \ldots < \lambda_k < 1$, and let n_i be the greatest integer less than or equal to $n\lambda_i + 1$. The λ_i partition the range of cumulative probabilities into a finite number of intervals, and thus a subjective element is implicit in their choice. Denote the cumulative distribution function associated with P_θ by $F(\cdot|\theta)$, and define the statistic

$$Y_n^2(\theta) = n\sum_{i=1}^{k}[(F(X'_{n_i}|\theta) - F(X'_{n_{i-1}}|\theta)) - p_i]^2/p_i \qquad [3]$$

where $p_i = \lambda_i - \lambda_{i-1}$, $i = 1, \ldots, k$. If $\hat{\theta}_n$ is an estimator that minimizes $Y_n^2(\theta)$, then under suitable regularity conditions the test statistic $Y_n^2(\hat{\theta}_n)$ is asymptotically distributed as chi-squared with $k - q - 1$ degrees of freedom, where q is the number of independent parameters.

Testing against Specified Alternatives

The above methods are general-purpose tests that aim at realizing test power for detecting a broad range of deviations from the model assumptions. Discussions of diagnostic tests and graphical methods for detecting specific deviations abound in treatments of many particular models. A general and widely applicable principle for deriving such tests is given by Neyman–Pearson log-likelihood ratio tests of nested models. For this purpose, a second, less constrained family of distributions $N = \{P_\eta, \ \eta \in \Psi\}$ is considered of which the original family M is a subset. For example, the second model may involve the same and additional predictors in the context of multiple linear regression; it may additionally contain interactions of higher order in the context of analysis-of-variance models or generalized linear models, and so forth. A so-called conditional model test is a test of H_0 versus H_1:

$$H_0 : Q \in M \quad \text{versus} \quad H_1 : Q \in N \setminus M$$

For this test, both θ and η are estimated by means of the maximum likelihood method under M and N, respectively, and $-2\log L$ is computed, where L is the ratio of the resulting likelihood values under the two models. Under suitable regularity conditions, the test statistic is distributed as chi-squared with degrees of freedom given by the difference in the number of independent parameters of the two models. The test power of this test is particularly large for detecting violations of constraints that M imposes over and above those imposed by N, but a significant result can also mean that constraints common to M and N are already violated.

Bayesian Model Checks and Criticisms

In Bayesian inference, a prior distribution has to be specified for the model parameters with density $g(\theta)$, and inference is then based on the posterior distribution of θ given the data $x = (x_1, \ldots, x_n)$ with density $f(\theta|x)$ proportional to the product of $g(\theta)$ and $f(x|\theta)$. Consequently, Bayesian model analyses check both the adequacy of the model specification in so-called model checks and the sensitivity of inferences relative to changes in the prior distribution in so-called robustness checks.

Robustness checks examine how sensitive the drawn inferences are as a function of alternative specifications of the prior. Frequently, different priors are plausible, and in hierarchical models priors can be complex, requiring many somewhat arbitrary decisions. Checking robustness involves specifying alternative priors and assessing the changes in inferences that

occur across the set of alternative priors. A couple of principled methods have been considered (O'Hagan and Forster, 2004; Chapter 8). They are not widely used because of the computational difficulties implied for realistically complex practical models.

Model checks attempt to explore the adequacy of a model without explicit reference to alternatives. One way to assess these questions is via so-called posterior predictive model checks (O'Hagan and Forster, 2004; Chapter 8). Given the data x, new data x^{pred} can be generated from the so-called posterior predictive distribution. Its density is $p(x^{\text{pred}}|x) = \int f(x^{\text{pred}}|\theta)f(\theta|x)\mathrm{d}\theta$. A test quantity $T(x,\theta)$ is then defined that is a function of the (new or old) data and of the parameters such that it quantifies specific deviations of the data from the model predictions. For example, T might be Pearson's chi-squared statistic of goodness of fit. The probability p of $T(x^{\text{pred}},\theta) > T(x,\theta)$ is then estimated under the joint distribution of (x^{pred},θ) given the observed data. This posterior p value can be conveniently estimated if a sample of the posterior distribution is obtained via Markov chain Monte Carlo methods in an application. The model is considered adequate with regard to the deviations quantified by T if this posterior p value is not small.

One way to think of this procedure is by analogy to classical assessments of model fit. The observed value of a test statistic is evaluated with reference to the distribution of the statistic generated from the model given the current parameter estimates. The parameter estimates stem from the posterior distribution, however, instead of from maximum likelihood estimation. For a critique of posterior predictive model checks, see O'Hagan and Forster (2004) (Chapter 8).

Within this framework, different kinds of simplification, extension, and variations have been explored. For example, it has been proposed to admit not only replicated data x^{pred} but also replicated parameters θ^{pred} into the definition of T and the reference distribution. Another approach, so-called predictive model checks, samples x^{pred} from the prior predictive distribution, with density given by $\int f(x|\theta)g(\theta)\mathrm{d}\theta$ and with T typically only a function of the data and not the parameters.

Posterior predictive model checks have been criticized as being too conservative because they test for discrepancies from the observed data using a reference distribution that has been shaped by that same data. Predictive model checks avoid this difficulty but can be of little diagnostic value if the prior is vague as well as not robust under different specifications of vague priors. A number of variants of these checks have been based upon partitioning the data set into two subsets, one of which is used to generate a posterior distribution of the model parameters and the rest to test for discrepancies with reference distributions derived from that posterior distribution (see the section on classical cross-validation methods below). Another principled approach to dealing with these difficulties has been proposed by Bayarri and Berger (2000).

Model Selection

In model testing, there is one distinguished model, and the objective is to test its validity. In model selection, there are several models, and the objective is to select one that best serves a given function such as estimation of certain common parameters or prediction. Frequently, the different models differ in complexity, usually indexed by the number of independent parameters, and most methods explicitly or implicitly incorporate a trade-off between fit and parsimony. Among the many different approaches that are discussed in this emerging field are model selection by classical hypothesis tests, discrepancy-based methods, bootstrap and cross-validation techniques, Bayes approaches, and information-theoretic approaches.

Model Selection by Classical Hypothesis Tests

In nested families of models, procedures for model selection have been proposed based on the classical hypothesis testing framework sketched above. So-called sequential model tests start with the model with the minimal number of constraints. During step k of the procedure, it is assumed that the model with k constraints holds, and is tested against the model with $k+1$ constraints. The sequence of tests is terminated at step l as soon as the first hypothesis with $l+1$ constraints is rejected. In multiple linear regression, the models are defined by the subset of predictors to be included in the equation, and automated sequential selection procedures based on hypothesis tests such as forward and backward stepwise selection have been considered (Jungeilges, 1992). For nonnested, disjoint models, selection by hypothesis testing is possible by means of a generalized likelihood ratio approach originally proposed by Cox (1961) or by integrating the models into a joint supermodel first (Atkinson, 1970).

Discrepancy-Based Methods

Another principled approach to model selection has been proposed by Linhart and Zuccini (1986). A discrepancy Δ measures the lack of fit of the underlying distribution Q relative to members P_θ of candidate models. It satisfies $\Delta(\theta) = \Delta(Q,P_\theta) \geq \Delta(Q,Q)$ for all θ.

Depending upon the purpose of the model selection exercise, different aspects of model fit may be important and may lead one to consider different discrepancies. Important general-purpose discrepancies are the following, where $F(\cdot)$ is the cumulative distribution function associated with Q and $F(\cdot|\theta)$ is the cumulative distribution function associated with P_θ. (For continuous random variables, the probability functions should be replaced by probability density functions and the sums by integrals.)

Kullback–Leibler discrepancy	$\Delta_{\text{K-L}}(\theta) = -E_Q \log f(x\|\theta)$,
Kolmogorov discrepancy	$\Delta_{\text{K}}(\theta) = \sup_x \|F(x) - F(x\|\theta)\|$,
Cramér–von Mises discrepancy	$\Delta_{\text{C-M}}(\theta) = E_{P\theta}(F(x) - F(x\|\theta))^2$,
Gauss discrepancy	$\Delta_{\text{G}}(\theta) = \sum_x (f(x) - f(x\|\theta))^2$,
Pearson chi-squared discrepancy	$\Delta_{\text{P}}(\theta) = \sum_x (f(x) - f(x\|\theta))^2/f(x\|\theta)$,
Neyman chi-squared discrepancy	$\Delta_{\text{N}}(\theta) = \sum_x (f(x) - f(x\|\theta))^2/f(x)$.

For a given model, the discrepancy due to approximation is defined as the discrepancy $\Delta(\theta_0)$ of that member P_{θ_0} of the model that minimizes $\Delta(Q,P_\theta)$. It is sometimes also called the model bias, the model error, or the degree of misspecification. For a given model and method of estimating θ, the discrepancy between P_{θ_0} and the estimated distribution $P_{\hat{\theta}}$, $\Delta(P_{\theta_0}, P_{\hat{\theta}})$, is

called the discrepancy due to estimation. It is sometimes also called the estimation variance. Finally, the overall discrepancy is the discrepancy of the underlying distribution and the fitted distribution, $\Delta(Q, P_{\hat{\theta}})$. In many of the cases of interest, the overall discrepancy is the sum of the two component discrepancies, but even when it is not, the overall discrepancy is still a monotone function of both component discrepancies.

It is interesting to consider how the component discrepancies behave as model complexity increases. As the model becomes less constrained, the discrepancy due to approximation will tend to decrease, because the model will be able to approximate the true distribution more closely. On the other hand, the discrepancy due to estimation will simultaneously tend to increase because complex models have a greater propensity to capitalize on chance and to be misled by chance fluctuations in the sample. Thus, the overall discrepancy represents a trade-off between the ability to fit and the propensity to capitalize on error.

In this approach, selection is based on estimated expected discrepancies, where expectation is taken with respect to the underlying distribution. An estimator of the expected discrepancy is called a criterion, and the model that gives rise to the smallest criterion is selected.

The derivation of criteria can be a difficult technical issue. In some contexts, unbiased estimators can be derived in the finite-sample case. For example, in the context of multiple linear regression, the well-known variable selection criteria S_p and C_p can be thus derived as (monotone transformations of) unbiased estimators of discrepancies based on errors of prediction (Linhart and Zuccini, 1986). In many instances, unbiased estimators cannot be derived. In these cases, asymptotic methods, bootstrap methods, and cross-validation techniques can be used.

For example, when the underlying distribution is a member of model M, an asymptotically unbiased criterion based on the Kullback–Leibler discrepancy is in fact AIC (divided by $2n$):

$$\mathrm{AIC} = -2\log f(x_1, \ldots, x_n | \hat{\theta}_n) + 2q$$

where $f(x_1, \ldots, x_n|\theta)$ is the likelihood of the data $x_1, \ldots, x_n$, and estimation is based on the maximum likelihood method. Even if Q is not in M, AIC/$(2n)$ has been argued to remain a satisfactory approximation of the Kullback–Leibler criterion as long as the model is not grossly misspecified (Linhart and Zuccini, 1986).

A small-sample correction of AIC is $\mathrm{AIC_c}$ given by

$$\mathrm{AIC_c} = \mathrm{AIC} + 2q\frac{q+1}{n-q-1}$$

It provides a better approximation of the Kullback–Leibler criterion in certain situations.

Bootstrap Techniques

Bootstrap techniques provide another means of estimating expected discrepancies that are widely applicable. In the bootstrap method, the unknown distribution Q is replaced by Q_n, which assigns probability mass $1/n$ to each observed value x_i, $i = 1, \ldots, n$. This makes it possible to compute expected discrepancies when an explicit formula is available or to use Monte Carlo methods to estimate expected discrepancies to any desired degree of accuracy. Expectation is with respect to Q_n rather than Q, however, and the bootstrap criterion has a downward bias (Chung et al., 1996).

Cross-Validation Techniques

In cross-validation, the data are divided into two subsamples, a calibration sample of size $n - \nu$ and a validation sample of size ν. The first sample is used to estimate the model; the second is used to estimate the expected discrepancy. Cross-validation techniques for model selection use a small ν, typically $\nu = 1$, but repeat the above steps for all possible subdivisions of the sample data into two subsamples of the required sizes. The cross-validation criterion is the average, over these repetitions, of the estimated expected discrepancies. When $\nu = 1$, this method is called one-item out cross-validation. Under many circumstances, the resulting cross-validatory criterion is straightforward to compute and is an estimator of the expected discrepancy for a sample of size $n - \nu$ (Linhart and Zuccini, 1986).

Bayesian Model Selection

Another principled approach to model selection has been proposed within the framework of Bayesian statistics. In this approach, each model M is seen as potentially containing the true probability distribution, and an a priori probability, $P(M)$, for this event is assigned to each model. Based on the data D, the posterior probabilities of the models, $P(M|D)$, are then computed, and the model with the largest posterior probability is selected. Another possibility is to avoid selection of one specific model altogether, and to use instead the posterior distribution, which averages over the different models by weighting each model with its posterior probability. This is called model averaging. In addition to an a priori probability for each model, an a priori probability has to be specified for the distribution of each model's parameters. Computing the posterior probabilities can be a formidable task.

For example, consider the case of just two models M_1 and M_2 and data D. Selection is based on the posterior odds,

$$\frac{P(M_1|D)}{P(M_2|D)} = \frac{P(D|M_1)\,P(M_1)}{P(D|M_2)\,P(M_2)}$$

such that M_1 is selected if the posterior odds exceed one and M_2 is selected otherwise. The first quotient on the right side of the above equation is called the Bayes factor, and it is equal to the posterior odds ratio, if the prior odds ratio is one. Bayes factors are known to be much more sensitive to the choice of the prior distributions than is Bayesian estimation of parameters of interest (O'Hagan and Forster, 2004; Chapter 7).

Another index is the BIC:

$$\mathrm{BIC} = -2\log f(x_1, \ldots, x_n | \hat{\theta}_n) + q\log(n)$$

where $f(x_1, \ldots, x_n|\theta)$ is the likelihood of the data $x_1, \ldots, x_n$, and estimation is based on the maximum likelihood method. It can be shown that selecting the model with the smaller value of the BIC is asymptotically equivalent to selecting according to the Bayes factor. Thus, the index BIC can be used to obtain a large-sample approximation of the Bayes factor.

The deviance information criterion (DIC) is another Bayesian model-selection index structured like AIC and BIC, in

that it comprises a term quantifying the lack of model fit and a term penalizing model complexity (O'Hagan and Forster, 2004; Chapter 7). The latter term is of interest in its own right, in that it is interpreted as the effective number of parameters. It is smaller than the actual number of parameters to the extent to which the model parameters are constrained by dependencies in the data or the prior. DIC can be conveniently computed on the basis of the output from Markov chain Monte Carlo methods of sampling from the posterior distribution. A point estimate of the parameter estimates is also required.

Model Selection Following the Minimum Description Length Principle

A different idea is pursued by the minimum description length approach. Roughly, a model reduces the complexity of a code (e.g., a string of binary values) needed to describe the data, because only the model and its estimated parameters as well as the residuals have to be encoded, but not the original data, once the model has been fit. In as much as the residuals show less variability than the original data, a good model reduces the code needed to describe the data set. The code length is a function of both the model's complexity and its ability to account for the data (Grünwald, 2007). In the present context, the principle leads to the NML index for model selection. Much like AIC and BIC, the index adds minus the maximum log-likelihood of the data given the model and a penalty term for the model's flexibility. The penalty is given by the logarithm of the sum of maximum likelihood values summed over the entire set of possible data patterns $\gamma = (\gamma_1, \ldots, \gamma_n)$ that might in principle occur in the experimental setting. NML is thus given by (again for continuous random variables, the sum should be replaced by an integral)

$$\mathrm{NML} = -\log f(x_1, \ldots, x_n | \hat{\theta}_n) + \sum_{\gamma} f(\gamma | \hat{\theta}_n(\gamma))$$

where $\hat{\theta}_n(\gamma)$ is the maximum likelihood estimate of the model parameters for data pattern γ. The penalty term, $\sum_{\gamma} f(\gamma | \hat{\theta}_n(\gamma))$, is a measure of the model's ability to fit data in general, whatever the data. The resulting model-selection index is principled and has a couple of desirable properties (Grünwald, 2007). For example, the penalty terms $2q$ and $q \log(n)$ in AIC and BIC, respectively, penalize models based on the number of parameters and (for BIC) sample size, whereas functional form plays no role. However, an additional parameter can have anything between a dramatic influence on a model's flexibility in fitting data in general and a negligible influence, depending upon how the parameter enters into the model equations. For example, constraining a parameter to range only in a certain restricted interval makes no difference in computing the penalty terms in AIC and BIC, but it appropriately leads to a decreased penalty term in NML. Like for BIC, model selection by NML is asymptotically linked to model selection by the Bayes factor (Grünwald, 2007; Chapter 14).

The NML index is often difficult to compute. An asymptotic approximation is the Fisher information approximation given by

$$\mathrm{FIA} = -\log f(x_1, \ldots, x_n | \hat{\theta}_n) + \frac{q}{2} \log \frac{n}{2\pi} + \int \sqrt{\det I(\theta)} \mathrm{d}\theta$$

where I is the so-called Fisher information matrix of the model for a sample of size one. The Fisher information matrix is the matrix of the expected second partial derivatives of the model's log-likelihood function. As can be seen, the index is similar to BIC (when multiplied by two). The term involving the Fisher information matrix can be seen as a measure of model flexibility due to functional form.

Model Selection and Testing: Concluding Remarks

Theoretical results show that BIC and NML identify the correct model with probability converging to one, as the sample size increases, whereas a similar asymptotic consistency is not given for AIC (Jungeilges, 1992). However, most distributions underlying real data are likely to be much more complex than the most complex model considered for selection. Under this premise, all the above selection methods favor the most complex models among the considered models as sample size increases, because estimation variance, but not model bias, converges to zero as n goes to infinity. That is, in large samples, selection is dominated by the degree of misspecification of given models so that nonparsimonious models with more ability to approximate the underlying complex distribution are selected. Similarly, in this situation, any model is eventually rejected in model testing as the test power of model tests for detecting even tiny model violations increases with increasing sample size.

Another class of problems is subsumed under the label model selection bias (Chatfield, 1995). Model selection criteria are themselves random variables and thus subject to random error. As a consequence, which model is selected for further inference or prediction is uncertain, and there may be a substantial probability that another model is chosen if the model selection procedure is repeated on the basis of a new random sample of the data. Note that this is a fundamental problem that also applies to criteria based on cross-validation and to Bayesian model selection.

This has several consequences. The criterion value of the selected model will in general appear too good, because overfitting may have contributed to the model's eventual selection success, and nominal standard errors of parameter estimates and nominal levels of significance tests based on the selected model will be incorrect because they do not take model uncertainty into account. Several approaches are being discussed for dealing with this issue. In Bayesian model selection, model uncertainty can be explicitly incorporated by model averaging (see above). Furthermore, through appropriate bootstrap and cross-validation techniques, model selection can be explicitly built into statistical procedures (Hjorth, 1994).

Abstract

This article focuses on dynamic models of endogenous interpersonal influences unfolding in networks, that is, a social process in which the displayed emotional, attitudinal, or behavioral orientations of individuals toward a common object are affected by the displayed orientations of other individuals toward the same object. A large empirical literature on interpersonal influence exists in the social sciences, which presents particular useful constraints on the formal architecture of this class of dynamic models. Research on these dynamic models is an accelerating interdisciplinary enterprise that includes contributions from the social, natural, and engineering sciences. The article outlines the core constructs and measurement models of this field, and details its engagement with the postulate of an influence process based on convex combinations of individuals' heterogeneous orientations toward common objects of their social environments.

Introduction

This article focuses on dynamic models of endogenous interpersonal influences unfolding in networks, that is, a social process in which the displayed emotional, attitudinal, or behavioral orientations of individuals toward a common object are affected by the displayed orientations of other individuals toward the same object. Because the domain of such objects is large, dynamic models of influence in networks have ubiquitous relevance in the social sciences. The object may be a particular issue, event, behavior, individual, commodity, institution, regime, political party, ethnic group, tribe, religion, or nation (i.e., any common focus of attention and arousal in a population of $n \geq 2$ individuals). The existence of endogenous interpersonal influences is a core postulate of social psychology. The postulate allows for individual differences of openness or closure to interpersonal influence.

The elementary unit of endogenous interpersonal influence is a *direct* influence relation for an ordered pair of individuals (i,j) in which individual j's emotional, attitudinal, or behavioral orientation toward a particular object is visible and salient to individual i. An invisible orientation cannot be directly influential, and a visible orientation may be discounted. The influence relation may be represented by the directed line $i \leftarrow j$, which indicates that j's orientation has a direct influence on i's orientation, or by $i \rightarrow j$, which indicates that j's orientation is accorded influence by i. This representation includes loops, $i \rightarrow i$, which indicate that i accords some weight to his or her own orientation.

With respect to direct influence relations, the core unsettled problem in this field is the discovery of a suitable formalization of the 'within-the-skin' mechanism – the cognitive algebra – by which each individual synthesizes the direct, heterogeneous orientations of other individuals, as well as his or her own orientation, toward an object. Some such synthesis must occur when an individual's orientation has been influenced by the orientations of others. Is the modified orientation a linear or nonlinear function of these orientations? Is it a convex combination? How does the individual's own orientation enter into the synthesis, and, in particular, when and how is the individual's initial orientation involved? Is it a first-order or higher order difference function? The specification remains an open question, although progress has been made on it. The available evidence comes from cognitive science (e.g., Anderson, 1981, 1991) and from empirical assessments of the predictions of dynamic models that incorporate particular assumptions about the cognitive algebra. The evidence points to a convex combination of orientations.

The more complex unit of endogenous interpersonal influence is a *total* influence relation for each ordered pair of individuals (i,j) in which individual j's orientation has influenced i's orientation on the basis of the direct and indirect flows of influence in a network. These flows are generated by the within-the-skin mechanism with which each member of an influence network cognitively synthesizes heterogeneous orientations. As individuals modify their orientations, each individual may be located in a changing landscape of orientations, and repetitive responses to these orientations enable indirect influences. The formal architecture of a model of influence in networks may or may not allow solutions of the total influence for each (i,j) ordered pair of an influence system.

This article concentrates on a class of dynamic models of influence in networks that allows the quantification of total influences on orientations toward an object, where the orientations are values in a defined interval on the real number line, and might be any number in this interval. Such orientations may be multidimensional. They also may be periodically displayed as categorical orientations that are epiphenomenal manifestations of individuals' real, more nuanced orientations toward an object.

Constraints on Mathematical Imagination

A massive empirical literature on interpersonal influence exists in the social sciences, from which findings may be extracted that have an important bearing on the formal architecture of models of influence in networks. Friedkin and Johnsen (2011) provide a portal into the social-psychological literature on group dynamics. Formal models of influence in networks vary in their attention to this literature and the extent to which their simplifying assumptions are constrained by robust generic

observations of the developed and developing lines of empirical work on social influence. Such empirical observations do exist, and three are highlighted; for their more detailed treatment, and access to the empirical studies upon which they are based, see Friedkin and Johnsen (2011).

First, individuals' extents of openness versus closure to interpersonal influence on a particular issue are heterogeneous. There is no universal constant of susceptibility to interpersonal influence. Heterogeneity extends to individuals' accorded influences: an individual is rarely accorded equal influence by different individuals, and different individuals are rarely accorded equal influence by the same individual. Individual differences are nonignorable and are based on numerous individual, relational, and contextual variables that affect individuals' openness to interpersonal influence and the amount of influence accorded to particular persons. Endogenous interpersonal influences involve *embodied* orientations, i.e., orientations toward an object that are displayed by particular individuals, and perforce are confounded with diverse features of not just the individuals who are conveying their orientations but also their interpersonal relationships. As a consequence, the basis of a direct influence relation, $i \rightarrow j$, in which i accords some weight to j's orientation, is complex, and simplifying homogeneity assumptions about the values of these relations are not credible. Empirical investigation of a model of influence in networks of size $n > 2$ poses a generalized three-body problem that requires direct measures of the network members' extents of openness to interpersonal influence and their accorded influences to other individuals.

Second, an important robust finding pertains to the formally attractive postulate that the value of the $i \rightarrow j$ accorded influence at time t may be simplified to a function of the time t orientations of those individuals whose orientations are visible to individual i. This postulate is attractive because, with it, a group's vector of initial orientations may be employed to specify the group's initial influence network and its temporal change, as orientations are modified, within a fixed structure of interpersonal visibility. Festinger's (1954) social comparison theory is a classic assertion of this postulate, and numerous models of influence in networks incorporate it. The accumulated empirical evidence does not support its employment as a reliable specification of influence networks. The mixed empirical findings in the literature on this specification are consistent with the conclusion that each direct influence relation, $i \rightarrow j$, in which i accords some weight to j's orientation, is the resultant of an idiosyncratic mixture of bases.

Third, interpersonal influences in networks generate various generic distributions of orientations. The emergent distribution may be a consensus, or it may be an influenced array of positions with unresolved disagreements. Both outcomes occur with noteworthy frequencies, even in *strongly connected* influence networks (i.e., networks in which one or more paths exist from i to j, and from j to i, for all i and j). A formal model of influence in networks must be consistent with both. Many proposed models are not. Hence, Abelson's (1964: 153) famous complaint: "Since universal ultimate agreement is [a] ubiquitous outcome of a very broad class of mathematical models, we are naturally led to inquire what on earth one must assume in order to generate the bimodal outcomes of community cleavage studies". When the outcome is consensus, it may be a settlement on an initial position of one of the members of a group, including the minimum or maximum (most extreme) initial position of the group members, or on a compromise position that is not the initial position of any group member. While the relative frequency of each type of consensus outcome varies depending on the experimental design, each type has been observed with noteworthy frequency in samples of small groups. Hence, formal models that exclude these frequently occurring generic outcomes have limited applicability.

Finally, and remarkably, individuals' emergent orientations are rarely more extreme than the minimum or maximum value of group members' initial orientations. In the special circumstance of an initial consensus, the consensus position is maintained unaltered by groups: the issue is considered settled, and the group will move on to the next issue when a sequence of issues is being dealt with. This robust finding applies to judgmental issues with no correct issue position, and to intellective issues with a correct position that may or may not be apprehended. On intellective issues, groups rarely question and alter an incorrect initial consensus. On both types of issues, in the absence of an initial consensus, discussions of an issue rarely generate positions that are outside the range of the initial positions of the group members. If this robust finding extends to multidimensional issues, then the general rule is that emergent influenced positions are constrained to the *convex hull* of a group's initial positions. Observed violations of this rule are rare and strongly support its employment as a simplifying formal constraint. This constraint is consistent with the assumption of a cognitive algebra based on a convex combination of orientations.

Influence Networks

The elementary units of endogenous interpersonal influence form an influence network, that is, ordered pairs of individuals (i,j) in which individual j's orientation toward a particular object is visible and salient to individual i, when such pairs are members of the set of ordered pairs defined by a population of $n \geq 2$ individuals with orientations toward a common object. Let $G(V,E)$ denote this network, where V is the set of n individuals, and E is the set of ordered pairs with a directed line $i \rightarrow j$ indicating that i accords some influence to j's displayed orientation toward the common object. This network may be described as an $n \times n$ matrix $\mathbf{G} = [g_{ij}]$ of values, with $g_{ij} = 0$ indicating the absence of an $i \rightarrow j$ relation, and $g_{ij} \neq 0$ indicating its existence and value, for each (i,j) ordered pair.

Analysis may focus on this global common-object network, or on one or more of its weakly connected components when multiple components exist. If G is transformed into an undirected graph $G \rightarrow \tilde{G}$, in which $i - j$ exists if and only if either $i \rightarrow j$ or $j \rightarrow i$ exists, then a weak component of G is a maximal connected subgraph of $\tilde{G}$. A weakly connected component is the minimal criterion of a *coherent* influence network within a population oriented to a common object; in other words, such a network does not exclude any individual who is accorded influence by one or more of its members, nor does it exclude

any individual who accords influence to one or more of its members, with respect to the common object. In particular, if i is included in the network and the accorded influences $i \rightarrow k \leftarrow j$ exist, then both k and j also must be included in the network. The collection of these disconnected components is the global common-object network. Note that each weak component may include individuals who are closed to interpersonal influence but accorded influence by at least one member of the component. Also note that a component, which satisfies the condition of weak connectivity, may be a component with a 'higher' connectivity category: it will be a strongly connected component if one or more paths exist from i to j, and from j to i, for each of its (i,j) unordered pairs; and it will be a unilaterally connected component if one or more paths exist from i to j, or from j to i, for each of its (i,j) unordered pairs (these standard definitions of a network's connectivity category (strong, unilateral, or weak) are such that strong $\Rightarrow$ unilateral $\Rightarrow$ weak connectivity).

The influence network $G(V,E)$ is a valued network for which homogeneity assumptions on these values are suspect. Homogeneity assumptions include constraining the main diagonal values of $\mathbf{G}$ to zero; constraining nonzero values of each row of $\mathbf{G}$ to the same value, which may vary from row to row; and constraining the nonzero values of each column of $\mathbf{G}$ to the same value, which may vary from column to column. The first is suspect because it assumes that all individuals accord no weight to their own orientations. The second is suspect because it assumes that all individuals do not discriminate among the orientations of other persons to whom they accord some influence. The third is suspect because it assumes that all individuals who accord influence to a particular individual will accord the same amount of influence to that person.

An important implication of a formal model that relaxes homogeneity assumptions is its demand for measurement models of $\mathbf{G}$ that are commensurate with the possibility of substantial heterogeneity. An outstanding problem is the lack of research on such measurement models. Investigations often employ measurement models of influence networks that draw on structural features of interpersonal contact networks. The availability of contact data is a convenience, which leaves open the problem of developing a measurement model that allows for heterogeneous accorded influences, including a measure of the extent to which each individual is open or closed to interpersonal influence on his or her orientations toward a particular object. Although regular contact is an important basis of interpersonal influence, it is not a necessary or sufficient condition of the interpersonal visibility and salience upon which influence is based. Currently, the most direct approach to a measurement model, and the approach that most closely corresponds to the cognitive foundations of accorded influence, is one that draws on individuals' subjective self-reported accorded weights to self and particular others. A detailed assessment of this measurement approach appears in Friedkin and Johnsen (2011), where 450 issue-specific influence networks are examined. As the implications of dealing with influence network structures are fleshed out, the measurement models of these structures will surely become an increasing focus of attention and refinement.

During some temporal period, $t = 1,2,\ldots,k$, the influence network $G(V,E)$ may be a fixed or changing construct with respect to V, E, or both. The network may be fixed by strongly constraining antecedent conditions, or subject to random disturbances, or a structure that evolves in a systematic way during the period. It may be a structure that is quickly constructed into a stable form by individuals engaged with a specific object. It may be a structure that applies to different objects, or an object-specific structure. Models of influence in networks are partitioned into two broad classes: those that assume a fixed network and those that do not. Models that allow structural changes of the influence network may or may not be researchable, as they present more or less demanding challenges for investigators interested in securing empirical supports for such models.

As Odysseus was forced to choose between Scylla and Charybdis, and chose the less challenging option (Scylla), most lines of research on models of influence have avoided dealing with the advancement of formalizations of an influence process that unfolds in a changing network, and have focused on the advancement of formalizations of an influence process that unfolds in a fixed network (these fixed-structure formalizations include models in which the edges of G are active or inactive with static probabilities). Even so, work on models that allow and formalize network evolution is accelerating. The work on structural change is a large leap into the unknown, down the middle of the Strait of Messina, which simultaneously grapples with Scylla and Charybdis. The approach necessarily combines (1) a formalization of the mechanism by which each individual cognitively synthesizes orientations of other individuals, as well as his or her orientation, toward an object; and (2) ancillary formalizations that temporally modify the network in which the influence mechanism unfolds. The assumption of a fixed network reduces the number of a model's moving parts, and usefully serves to concentrate attention on the fundamental predicates of the influence mechanism. The assumption requires a thoughtful selection of field settings and experimental designs in which it is not grossly violated.

The literature on influence networks presents a remarkable interdisciplinary convergence to a specification of $\mathbf{G}$ in which $0 \leq g_{ij} \leq 1$ for all i and j, and $\sum_{j=1}^{n} g_{ij} = 1$ for all i. This important special case of $\mathbf{G}$ will be denoted as $\mathbf{W}$. The accorded values $\{w_{i1}, w_{i2}, \ldots, w_{in}\}$ for each i are the direct relative weights accorded by i to the orientation of each member of the network. If $w_{ii} = 1$, then the individual is completely closed to interpersonal influence, $\sum_{j \neq i}^{n} w_{ij} = 0$. If $w_{ii} = 0$, then the individual is completely open to interpersonal influence, $\sum_{j \neq i}^{n} w_{ij} = 1$. A subset of these interpersonal weights will be 0 in cases of invisible orientations, and others will be 0 in cases of visible but completely discounted orientations. The importance of this specification is indicated by the consequence of a loss of confidence in it: if confidence in it were substantially eroded, then a large number of models of influence in networks would be set aside.

Direct measures of the accorded influences entailed in $\mathbf{W}$ have been based on individuals' subjective self-reported allocations of weights to self and particular others on a specific issue. Proxy measures based on contact networks, which allow heterogeneity and do not restrict direct influence to contact relations, have been based on measures of structural centrality to specify individuals' extents of openness or closure to interpersonal influence, and on measures of structural proximity to

specify the interpersonal accorded weights for each individual (e.g., Friedkin, 1998, 2001). In such cases, when the investigator's measurement model of susceptibility is different from the measurement model for accorded interpersonal influence, the two measurement models may be combined to form **W** as follows:

$$\mathbf{W} = \mathbf{AC} + \mathbf{I} - \mathbf{A} \qquad [1]$$

where $\mathbf{A} = \mathrm{diag}(a_{11}, a_{22}, \ldots, a_{nn})$, with $0 \le a_{ii} \le 1$ for all i, is the measure of an individual's openness to interpersonal influence; and $\mathbf{C} = [c_{ij}]$, with $0 \le c_{ij} \le 1$ for all i and j, and $c_{ii} = 0$ for all i is the measure of the relative interpersonal weights accorded to others. Here, $\sum_j^n c_{ij} = 1$ if $a_{ii} > 0$, and $\sum_j^n c_{ij} = 0$ if $a_{ii} = 0$:

$$w_{ij} = \begin{cases} 1 - a_{ii} & \text{for } i = j \\ 0 & \text{for } i \neq j, \text{ with } \sum_j^n c_{ij} = 0, \text{ if } a_{ii} = 0 \\ a_{ii}c_{ij} + 1 - a_{ii} & \text{for } i \neq j, \text{ with } \sum_j^n c_{ij} = 1, \text{ if } a_{ii} > 0 \end{cases} \qquad [2]$$

The decomposition assumes $a_{ii} = 1 - w_{ii} = \sum_{j \neq i}^n w_{ij}$, that is, an individual's extent of openness to interpersonal influences is equivalent to the aggregate interpersonal weight that the individual accords to others.

Formalization of the Influence Mechanism

Models of influence in networks often bypass the complex problem of specifying the antecedents of direct influence relations and, instead, focus on the advancement of suitable formalizations of the process of interpersonal influence. Two specifications of the process are prominent and distinguished by their focus on either nominal (i.e., categorical) orientations or real (i.e., quantitative) orientations that allow all values of an interval on the real number line. For nominal orientations, a 'threshold mechanism' is postulated in which an individual's selection among mutually exclusive (typically binary) options is displayed when the influenced value of a quantitative variable (usually conceptualized as a pressure or inclination to manifest a particular choice or behavior) reaches or exceeds a threshold value (Granovetter, 1978; Watts and Dodds, 2007). For real orientations, an 'averaging mechanism' is postulated in which an individual's influenced orientation is a weighted average of other individuals' orientations, as well as the individual's own orientation (DeGroot, 1974; Friedkin and Johnsen, 1990, 1999, 2011).

The theoretical distinction between these two mechanisms is narrowed when individuals' nominal displays are epiphenomenal manifestations of real orientations formed by a weighted averaging mechanism. Individuals with the same nominal choice may vary markedly in the strength of their orientations; individuals with different nominal choices may include more or less opposing orientations. Threshold and averaging mechanisms are not inconsistent, and both may be maintained. However, if real orientations are always implicated in nominal choices and the latter are inexact indicators of real orientations, then the general versus restricted accuracy of a threshold mechanism may be questioned. The postulate of ubiquitous real orientations is importantly supported by the work of Bargh and Ferguson (2000) and others on the automaticity of attitudes. The enactment of a behavior is constrained by various circumstances; behavioral inclinations, to do or not do something, may or may not be manifested. The predicate of an influence of action-upon-action is not universally applicable. In contrast, attitudinal orientations to objects appear to be an automatic response to objects, and their displays may be taken as a general predicate of formal models of endogenous interpersonal influences in networks. Models of endogenous interpersonal influences on attitudinal orientations toward objects leave open the elaboration of the linkages of attitudes with individuals' emotions and actions toward specific objects. With respect to the attitude–behavior linkage, attitudes may be included as an antecedent condition of the probability of an action among other antecedent conditions relevant to the explanation of the particular behavior (Friedkin, 2010).

The field presents numerous formalizations of the mechanism by which individuals cognitively synthesize the orientations of others toward an object, as well as own orientation, during the temporal process of interpersonal influence. This author's assumptions are that there is one to-be-discovered mechanism operating on attitudes by which the mind accomplishes the synthesis, and that this mechanism can formalized. Treating the mechanism as a rational calculation is suspect, when neither the orientations that are synthesized nor the accorded influences that are implicated in it may rest on rational calculations. Although the slow hard work of rational calculation may be done by some individuals, the quick work of an automatic natural heuristic mechanism appears to be a more generally accurate basis on which to construct models of influence in networks. With the accumulating findings of the cognitive revolution in social psychology, indicating ubiquitous heuristic mechanisms, it has become increasingly anomalous to assume rational calculation as the main basis of interpersonal influence systems (Kahneman, 2011; Kahneman et al., 1982).

For a fixed influence network, models of influence in the network necessarily involve an additional assumption about the *sequence* of interpersonal influences. Three simplifying sequence specifications are that (1) the individuals randomly broadcast their orientations in a temporal sequence, (2) dyads are randomly activated in a temporal sequence, and (3) all individuals are simultaneously directly influenced by all of their visible and salient orientations at each time t in a temporal sequence.

This article concentrates on the third class of sequencing formalizations, consistent with the discrete time linear model:

$$\mathbf{Y}^{(t+1)} = \mathbf{AWY}^{(t)} + \mathbf{BY}^{(1)}, \quad t = 1, 2, \ldots \qquad [3]$$

where $\mathbf{A} = \mathrm{diag}\ (a_{11}, a_{22}, \ldots, a_{nn})$, with $0 \le a_{ii} \le 1$ for each i; $\mathbf{B} = \mathrm{diag}\ (b_{11}, b_{22}, \ldots, b_{nn})$; $\mathbf{Y}^{(t)} = [y_{ik}^{(t)}]$ is an $n \times m$ matrix of values, which allows all values of an interval on the real number line; and k is the kth dimension of the time t orientation of each individual toward a particular object. The formalization permits solutions of total influence for each ordered pair of an influence system (i.e., the net direct and indirect influence of j on i, for each (i,j) ordered pair). With it, various theorems of linear algebra are applicable. Notably, for suitable **W**, $\lim_{k \to \infty} \mathbf{W}^k = \mathbf{W}^\infty$ exists, and for suitable **AW**, $\lim_{k \to \infty} [\mathbf{I} + \mathbf{AW} + (\mathbf{AW})^2 + (\mathbf{AW})^3 + \ldots + (\mathbf{AW})^k] = (\mathbf{I} - \mathbf{AW})^{-1}$

exists. Equilibrium orientations of the individuals, $\mathbf{Y}^{(\infty)}$, may or may not be attained, depending on the conditions under which the influence process unfolds. The formal architecture may be elaborated with a specification of the antecedents of the initial orientations of individuals $\mathbf{Y}^{(1)} \leftarrow \mathbf{X}$. It may also be elaborated with a specification of nominal (categorical) manifestations of the orientations of individuals, $\ddot{\mathbf{Y}}^{(t+1)} \leftarrow \mathbf{Y}^{(t+1)}$, where the special categorical nature of such manifestations are denoted by the 'double-dotted' $\mathbf{Y}^{(t+1)}$.

Not all special cases of this linear model are consistent with the constraint that emergent $\mathbf{Y}^{(t+1)}$ is in the convex hull of $\mathbf{Y}^{(1)}$. A seminal special case, consistent with this constraint, is obtained with $\mathbf{A} = \mathbf{I}$ and $\mathbf{B} = \mathbf{0}$:

$$\mathbf{Y}^{(t+1)} = \mathbf{W}\mathbf{Y}^{(t)}, t = 1, 2, \ldots .$$

The model is postulated by French (1956), Harary (1959), and DeGroot (1974). The within-the-skin mechanism is

$$y_{ik}^{(t+1)} = \sum_{j=1}^{n} w_{ij} y_{jk}^{(t)}$$

for the kth dimension of the orientation. The mechanism is a memoryless weighted averaging of the orientations that are accorded influence. The self-weight w_{ii} is the extent to which an individual is open or closed to interpersonal influence. The aggregate interpersonal weight, $1 - w_{ii} = \sum_{j \neq i} w_{ij}$, is distributed in the mind of i to other individuals. The equilibrium state of the system is $\mathbf{Y}^{(\infty)} = \mathbf{W}\mathbf{Y}^{(\infty)}$. Not all $\mathbf{W}$ allow equilibrium. Equilibrium is not attainable, for example, in an $n = 2$ influence system with $w_{11} = w_{22} = 0$ and $y_{1k}^{(1)} \neq y_{2k}^{(1)}$. The input–output formalization, obtained from the recursion, is $\mathbf{Y}^{(\infty)} = \mathbf{V}\mathbf{Y}^{(1)}$ when $\mathbf{V} \equiv \lim_{k \to \infty} \mathbf{W}^k = \mathbf{W}^{\infty}$ exists. The emergent values, $\mathbf{V} = [v_{ij}], 0 \leq v_{ij} \leq 1, \sum_{j=1}^{n} v_{ij} = 1$, are the total relative influences of each individual j on each member i of the influence system. Thus, the equilibrium orientation of each individual is a weighted average of the members' initial orientations, $y_{ik}^{(\infty)} = \sum_{j=1}^{n} v_{ij} y_{jk}^{(1)}$, on each dimension, where the weights are the total influences. The v_{ij} are not, of course, in the mind; their values are collective nontransparent resultants of the influence process unfolding in a network.

While the model allows heterogeneous influences and constrains influenced orientations to the convex hull of initial orientations, it presents a highly restricted set of conditions under which equilibrium disagreement will occur. In particular, in the domain of strongly connected influence networks, the generic form of $\mathbf{V}$, if it exists, is

$$\mathbf{V} = \begin{bmatrix} z_1 & z_2 & \cdots & z_n \\ z_1 & z_2 & \cdots & z_n \\ \vdots & \vdots & \ddots & z_n \\ z_1 & z_2 & \cdots & z_n \end{bmatrix}, \quad 0 \leq z_i \leq 1, \sum_{j=1}^{n} z_j = 1,$$

$$i = 1, 2, \ldots, n \qquad [4]$$

and the model's prediction is a consensus matrix $\mathbf{Y}^{(\infty)}$, with respect to the values of each of its one or more dimensions. In this case, an analytical solution for $\mathbf{z} = [z_1 \quad z_2 \quad \ldots \quad z_n]'$ is available from the left eigenvector of $\mathbf{W}$ for eigenvalue 1, that is, $\mathbf{x} = \mathbf{W}'\mathbf{x}$, whence $z_i = x_i / \sum_k^n x_k$.

The restrictive formal properties of this model motivated Friedkin and Johnsen's (1990, 1999, 2011) generalizations. With the constraint $\mathbf{B} = \mathbf{I} - \mathbf{A}$, the Friedkin–Johnsen model for a fixed influence network is

$$\mathbf{Y}^{(t+1)} = \mathbf{A}\mathbf{W}\mathbf{Y}^{(t)} + (\mathbf{I} - \mathbf{A})\mathbf{Y}^{(1)}, \quad t = 1, 2, \ldots . \qquad [5]$$

Clearly, with $\mathbf{A} = \mathbf{I}$, this model subsumes the French–Harary–DeGroot model as a special case. The formalized within-the-skin mechanism is

$$y_{ik}^{(t+1)} = a_{ii} \sum_{j=1}^{n} w_{ij} y_{jk}^{(t)} + (1 - a_{ii}) y_{ik}^{(1)} \qquad [6]$$

for the kth dimension of the orientation. The cognitive algebra remains a weighted averaging of the orientations that are accorded influence, but now it is a mechanism in which the initial orientation may not be 'forgotten': it disappears as a component of the synthesis if $a_{ii} = 1$, and remains a component otherwise. When the antecedent bases of an initial orientation include experiences, values, beliefs, and norms, the initial orientation toward an object may have enduring salience. The individual-level value $0 \leq a_{ii} \leq 1$ describes the extent to which an individual is closed or open to interpersonal influence. The *standard* form of this mechanism assumes $a_{ii} = 1 - w_{ii}$, for all i. With this constraint, the weight accorded to the initial orientation $1 - a_{ii}$ is equivalent to self-weight w_{ii}, and to the extent to which an individual is closed to interpersonal influence. The extent to which an individual is open to interpersonal influence (i.e., the aggregate interpersonal weight, $a_{ii} = 1 - w_{ii} = \sum_{j \neq i} w_{ij}$) is distributed in the mind of i to one or more other individuals.

A more general formalization of total influences than $\mathbf{V} \equiv \mathbf{W}^{\infty}$ is available with this mechanism. The partial and total influences emerge as follows:

$$\mathbf{Y}^{(2)} = \mathbf{A}\mathbf{W}\mathbf{Y}^{(1)} + (\mathbf{I} - \mathbf{A})\mathbf{Y}^{(1)} = \mathbf{V}^{(1)}\mathbf{Y}^{(1)}$$

where

$$\mathbf{V}^{(1)} = \mathbf{A}\mathbf{W} + (\mathbf{I} - \mathbf{A})$$

$$\mathbf{Y}^{(3)} = \mathbf{A}\mathbf{W}\mathbf{Y}^{(2)} + (\mathbf{I} - \mathbf{A})\mathbf{Y}^{(1)} = \mathbf{V}^{(2)}\mathbf{Y}^{(1)}$$

where

$$\mathbf{V}^{(2)} = (\mathbf{A}\mathbf{W})^2 + (\mathbf{A}\mathbf{W} + \mathbf{I})(\mathbf{I} - \mathbf{A}) = \mathbf{A}\mathbf{W}\mathbf{V}^{(1)} + (\mathbf{I} - \mathbf{A})$$

$$\mathbf{Y}^{(4)} = \mathbf{A}\mathbf{W}\mathbf{Y}^{(3)} + (\mathbf{I} - \mathbf{A})\mathbf{Y}^{(1)} = \mathbf{V}^{(3)}\mathbf{Y}^{(1)}$$

where

$$\begin{aligned} \mathbf{V}^{(3)} &= (\mathbf{A}\mathbf{W})^3 + [(\mathbf{A}\mathbf{W})^2 + \mathbf{A}\mathbf{W} + \mathbf{I}](\mathbf{I} - \mathbf{A}) \\ &= \mathbf{A}\mathbf{W}\mathbf{V}^{(2)} + (\mathbf{I} - \mathbf{A}) \end{aligned}$$

and so on. Note that the sequence $\mathbf{V}^{(1)}$, $\mathbf{V}^{(2)}$, $\mathbf{V}^{(3)}$, …, may be obtained by specifying the starting matrix $\mathbf{V}^{(1)} = \mathbf{A}\mathbf{W} + (\mathbf{I} - \mathbf{A})$ and recursively applying the formula $\mathbf{V}^{(t+1)} = \mathbf{A}\mathbf{W}\mathbf{V}^{(t)} + (\mathbf{I} - \mathbf{A})$ for $t = 1, 2, \ldots$ When $\mathbf{V} \equiv \lim_{t \to \infty} \mathbf{V}^{(t)}$ exists, the equilibrium matrix equations of the process are

$$\begin{aligned} \mathbf{Y}^{(\infty)} &= \mathbf{A}\mathbf{W}\mathbf{Y}^{(\infty)} + (\mathbf{I} - \mathbf{A})\mathbf{Y}^{(1)} \\ &= \mathbf{V}\mathbf{Y}^{(1)} \end{aligned} \qquad [7]$$

and we have for each group member i:

$$y_{ik}^{(\infty)} = \sum_{j=1}^{n} v_{ij} y_{jk}^{(1)} \qquad [8]$$

for the kth dimension of the orientation, where the values of the emergent $\mathbf{V} = [v_{ij}], 0 \le v_{ij} \le 1, \sum_{j=1}^{n} v_{ij} = 1$ are the relative total influences of each individual j on each member i of the influence system. The equilibrium orientation of each individual is a weighted average of the members' initial orientations. For $\mathbf{A} = \mathbf{I}$, this limit is $\mathbf{V} = \mathbf{W}^{\infty}$. For a nonsingular $\mathbf{I} - \mathbf{AW}$, it is $\mathbf{V} = (\mathbf{I} - \mathbf{AW})^{-1}(\mathbf{I} - \mathbf{A})$. In general, with

$$\mathbf{V}^{(1)} = \mathbf{AW} + (\mathbf{I} - \mathbf{A}) \qquad [9]$$

$$\mathbf{V}^{(t+1)} = \mathbf{AWV}^{(t)} + (\mathbf{I} - \mathbf{A}), \quad t = 1, 2, \ldots,$$

$\mathbf{V}$ is defined as the limit of the above recursion, when the limit exists.

It is useful to consider a prominent specification consistent with $\mathbf{Y}^{(t+1)} = \mathbf{AWY}^{(t)} + \mathbf{BY}^{(1)}$, which does not constrain $\mathbf{Y}^{(t+1)}$ to the convex hull of $\mathbf{Y}^{(1)}$. With the constraints $\mathbf{A} = \alpha\mathbf{I}$ and $\mathbf{B} = \mathbf{I}$, we have

$$\mathbf{Y}^{(t+1)} = \alpha\mathbf{WY}^{(t)} + \mathbf{Y}^{(1)}, \quad t = 1, 2, \ldots \qquad [10]$$

that is, a familiar discrete time dynamic model. With $0 < \alpha < 1$, the equilibrium state of the system is $\mathbf{Y}^{(\infty)} = \alpha\mathbf{WY}^{(\infty)} + \mathbf{Y}^{(1)}$, and its input–output formalization is $\mathbf{Y}^{(\infty)} = (\mathbf{I} - \alpha\mathbf{W})^{-1}\mathbf{Y}^{(1)}$ (for a one-dimensional orientation, the elaboration of the model with $\mathbf{y}^{(1)} = \mathbf{X\beta} + \mathbf{u}$ returns Ord's (1975) formalization and associated statistical approach to estimating the two unmeasured constructs $\{\alpha, \boldsymbol{\beta}\}$). This formalization does not necessarily constrain $\mathbf{Y}^{(\infty)}$ to the convex hull of $\mathbf{Y}^{(1)}$. The Friedkin–Johnsen formalization may be brought close to this model, $\mathbf{Y}^{(t+1)} = \alpha\mathbf{WY}^{(t)} + (1 - \alpha)\mathbf{Y}^{(1)}$ and $\mathbf{Y}^{(\infty)} = (\mathbf{I} - \alpha\mathbf{W})^{-1}(1 - \alpha)\mathbf{Y}^{(1)}$, so that the equilibrium predictions of the two models differ only by the factor $(1 - \alpha)$. The factor constrains $\mathbf{Y}^{(\infty)}$ to the convex hull of $\mathbf{Y}^{(1)}$. However, the $\mathbf{A} = \alpha\mathbf{I}$ homogeneity assumption is suspect.

Lastly, consider the constraint $\mathbf{B} = \beta(\mathbf{I} - \mathbf{A})$, with which $\mathbf{Y}^{(\infty)} = \beta\mathbf{VY}^{(1)}$, where $\mathbf{V}$ is the Friedkin–Johnsen $\mathbf{V}$. This generalization of the Friedkin–Johnsen model allows for breaches of the convex hull of $\mathbf{Y}^{(1)}$ with a scalar $\beta \neq 1$ that inflates or deflates the values of all orientations (Friedkin, 1999; Friedkin and Johnsen, 1990). This and the other special cases of $\mathbf{Y}^{(t+1)} = \mathbf{AWY}^{(t)} + \mathbf{BY}^{(1)}$, described in this article, are not exhaustive.

Illustration

Most formalizations of endogenous interpersonal influences deal with a one-dimensional $\mathbf{Y}^{(t)}$. The availability of multidimensional $\mathbf{Y}^{(t)}$ has not been exploited. To illustrate, consider persons who are prioritizing m alternatives or planning to distribute an amount of some resource over m alternatives, where each person's orientation is represented by the relative weight that the person accords to a particular alternative or by the proportion of available resources (e.g., time and funds) that the person believes should be allocated to each of the alternatives. Here, $\mathbf{Y}^{(t)} = [y_{ik}^{(t)}]$ is an $n \times m$ weight matrix with $0 \le y_{ik}^{(t)} \le 1$ for each person $i = 1, 2, \ldots, n$ and each alternative $k = 1, 2, \ldots, m$, such that $\sum_{k=1}^{m} y_{ik}^{(t)} = 1$ for all i. For such a $\mathbf{Y}^{(t)}$, a non-obvious property of the influence process specified by Friedkin and Johnsen is its preservation of the form of the issue (i.e., the weights assigned by each person to the m alternatives will sum to one at each time t). In general, from $\mathbf{Y}^{(t+1)} = \mathbf{V}^{(t)}\mathbf{Y}^{(1)}$, $\mathbf{Y}^{(t+1)}$ must be row-stochastic if $\mathbf{Y}^{(1)}$ is row-stochastic. Depending on the application, $\mathbf{Y}^{(t)}$ may be periodically displayed as categorical choices (e.g., persons may choose their most preferred alternatives):

$$\ddot{y}_{ik}^{(t)} = \begin{cases} 0 & \text{if } y_{ik}^{(t)} < \max(y_{i1}^{(t)}, y_{i2}^{(t)}, \ldots, y_{im}^{(t)}) \\ 1 & \text{if } y_{ik}^{(t)} = \max(y_{i1}^{(t)}, y_{i2}^{(t)}, \ldots, y_{im}^{(t)}) \end{cases} \qquad [11]$$

for all i at each time $t = 1, 2, 3, \ldots$, where this maximum value may occur for more than one alternative.

To make the illustration concrete, consider a group of four persons who are discussing three alternatives {A, B, C} and periodically displaying their most preferred alternative(s). Suppose that the displayed initial positions of the persons on this issue are

$$\mathbf{Y}^{(1)} = \begin{array}{c} \begin{array}{ccc} \text{A} & \text{B} & \text{C} \end{array} \\ \begin{bmatrix} .20 & .20 & .60 \\ .50 & .25 & .25 \\ .25 & .60 & .15 \\ 0 & 0 & 1 \end{bmatrix} \end{array} \qquad \ddot{\mathbf{Y}}^{(1)} = \begin{array}{c} \begin{array}{ccc} \text{A} & \text{B} & \text{C} \end{array} \\ \begin{bmatrix} 0 & 0 & 1 \\ 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{bmatrix} \end{array}$$

Person 1 accords .20 weight to the first two alternatives and .60 weight to the third alternative, person 2 accords .50 weight to the first alternative and .25 weight to the second and third alternatives, and so on. Interpersonal influences may alter these orientations and, depending on the influence network, produce consensus. If the influence network of the group is

$$\mathbf{W} = \begin{bmatrix} .500 & .250 & 0 & .250 \\ .100 & .100 & .200 & .600 \\ .100 & .200 & .600 & .100 \\ 0 & .300 & 0 & .700 \end{bmatrix}$$

then, from $\mathbf{Y}^{(t+1)} = \mathbf{AWY}^{(t)} + (\mathbf{I} - \mathbf{A})\mathbf{Y}^{(1)}$, with $a_{ii} = 1 - w_{ii}$ for all i,

$$\mathbf{Y}^{(2)} = \begin{array}{c} \begin{array}{ccc} \text{A} & \text{B} & \text{C} \end{array} \\ \begin{bmatrix} .213 & .181 & .606 \\ .158 & .174 & .669 \\ .258 & .532 & .210 \\ .045 & .023 & .933 \end{bmatrix} \end{array} \qquad \ddot{\mathbf{Y}}^{(1)} = \begin{array}{c} \begin{array}{ccc} \text{A} & \text{B} & \text{C} \end{array} \\ \begin{bmatrix} 0 & 0 & 1 \\ 0 & 0 & 1 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{bmatrix} \end{array}$$

$$\mathbf{Y}^{(3)} = \begin{bmatrix} .179 & .170 & .652 \\ .154 & .165 & .681 \\ .235 & .510 & .255 \\ .024 & .020 & .956 \end{bmatrix} \qquad \ddot{\mathbf{Y}}^{(1)} = \begin{bmatrix} 0 & 0 & 1 \\ 0 & 0 & 1 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{bmatrix}$$

$$\vdots$$

$$\mathbf{Y}^{(\infty)} = \begin{bmatrix} .156 & .162 & .682 \\ .122 & .153 & .726 \\ .219 & .499 & .282 \\ .014 & .017 & .969 \end{bmatrix} \qquad \ddot{\mathbf{Y}}^{(1)} = \begin{bmatrix} 0 & 0 & 1 \\ 0 & 0 & 1 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{bmatrix}$$

Person 1's initial preference for option C has been strengthened. Person 2's initial preference for option A has decisively switched to option C. Person 3's initial preference for option B has been maintained on a somewhat weakened basis. Person 4's initial strong preference for option C has been maintained. The influence system has generated a majority whose most preferred preference is option C.

Conclusion

The literature on models of influence in networks is substantially larger and more complex than is suggested by the focus of this article. There is no lack of imagination in the field in constructing such models. However, an intimate dance between theoreticians and experimentalists, which has served to dramatically advance particular fields of the natural sciences, is rare. My perspective on this body of work is captured by a lithograph which shows a logger, axe in hand, looking at a tree that he has just cut through: the tree, instead of toppling over, has floated upwards and the logger is standing dumbstruck, perhaps disappointed, at the result. Plausible formalizations may or may not be supported by detailed nontrivial empirical observations. For example, the demonstration that a particular model can generate a consensus or bipolar factions on an issue is important, since these generic types of outcomes have been observed, but many models can do the same and may differ markedly in the accuracy with which they predict the content of emergent orientations. Sustained lines of empirical inquiry on dynamic models of endogenous interpersonal influences unfolding in a network are surprisingly scarce.

Untested models with explorations (via simulation) of their formal properties are the rule. The main, and considerable, value of such work is the demonstration of what might be explained if the assumptions of the dynamic model are well founded. However, a more jaundiced perspective also is applicable: such explanations are easily obtained and not compelling in the absence of empirical evaluations of their predictions. While the judgment on what constitutes a compelling empirical assessment of a formal architecture may rest on different standards, the advancement of science has not suffered from its emphasis on parsimony and measured constructs. Note that the Friedkin–Johnsen model involves no unmeasured constructs. The predictions of the model are generated strictly on the basis of individuals' initial orientations $\mathbf{Y}^{(1)}$ and their influence network $\mathbf{W}$, for which measures may be, and have been, gotten.

A sustained line of empirical work has occurred on Friedkin–Johnsen's standard model. I close with a brief description of these supports, and in so doing emphasize the importance of obtaining the direct measures of individuals' initial orientations toward an object, which are involved in the evaluations conducted to date. The supports are based on experiments with small groups, in a standard design that obtains pre- and postdiscussion orientations, and measures of each group member's postdiscussion subjective accorded weights to self and particular others (i.e., each row of $\mathbf{W}$). I have previously noted that the employment of subjective weights is consistent with the cognitive foundations of the postulated mechanism, and have emphasized the importance of further work on measurement models of $\mathbf{W}$. The available evidence indicates that influence networks are issue specific and may differ for the same group of individuals as they consider a sequence of issues.

The laboratory experiments on the model have included designs in which members' interpersonal communications are constrained to dyadic interaction in telephonic communication networks with different structures of open lines of communication, and designs in which members are communicating via computers with broadcasts to all members of the group. The model's simplifying assumption on sequencing (i.e., all individuals simultaneously respond to all visible and salient orientations in a temporal sequence of state changes) does not appear be seriously misleading. Notably, in addition, the model has been evaluated in a quasi-experimental field setting, dealing with established book clubs who have met regularly face-to-face to discuss selected texts (Childress and Friedkin, 2012). The same design was employed, with measures of individuals' pre- and postdiscussion orientations toward a particular book, and measures of each group member's postdiscussion subjective accorded weights to self and particular others. Because these are enduring groups, an attempt was made to obtain a prediscussion measure of $\mathbf{W}$, under the expectation of a stable preestablished influence network. However, a substantial proportion of book club members disabled this measure with their expressions of doubt about 'tending' to be influenced by the same individuals across meetings; the subjects noted that while such a tendency sometimes occurs, their accord of influence and its distribution vary substantially from meeting to meeting depending on the subject matter of the book being discussed.

In each of the studies, the empirical analysis focused on the accuracy of the input–output formalization, that is, the predicted postdiscussion orientations $\hat{\mathbf{y}}^{(\infty)} = \mathbf{V}\mathbf{y}^{(1)}$, based on a one-dimensional measure of the vector of initial attitudes $\mathbf{y}^{(1)}$ and the subjective direct measure of each group's influence network $\mathbf{W}$, where the emergent total predicted influences are the elements of the matrix $\mathbf{V}$. The predicted postdiscussion orientations are elements of the vector $\hat{\mathbf{y}}^{(\infty)}$, and the predicted group-level mean orientation for each group is the mean value of the elements of this vector. Support for the model is indicated in group-level analyses of these data, where groups' postdiscussion mean orientations are regressed on their predicted mean orientations, and in multilevel mixed-effects regression analyses of individuals nested in groups (Rabe-Hesketh and Skrondal, 2008), where the dependent variable is individuals' postdiscussion orientations and the independent variables are individuals' predicted postdiscussion orientations and the predicted group-mean orientation.

In both the laboratory and field settings, significant effects of the model's predictors were maintained under controls for the individuals' initial orientations and the groups' initial mean orientations. With any model that constrains predictions to the convex hull of initial orientations, such controls are essential to the assessment of the model. If a model's predictions do not significantly contribute to explaining the direction and magnitude of departures of individuals' postdiscussion orientations from their prediscussion orientations, and departures of groups' postdiscussion mean orientations from their prediscussion mean orientations, then the approach (its particular

combination of measurement and formal models) must be rejected. To date, the Friedkin–Johnsen model has survived this test on six issues, with experiments conducted in laboratories of three universities and one field setting, under different conditions of pressure to reach consensus; under different types of, and more or less constrained, communication structures; and with datasets that were assembled by investigators other than Friedkin and Johnsen.

Subjective heterogeneity (i.e., a mind's idiosyncratic allocation of weights) is an important feature of accorded influences. This feature is subject to conditioning, and special cases of extreme conditioning can elevate an individual's openness to interpersonal influence and constrain the individual's accord of influence to particular other individuals. Social ecology and communication technology have implications for the pattern of interpersonal visibility of displayed orientations. Acknowledging such effects does not erode the fundamental postulate that influence networks are social cognition structures, assembled by the weights that individuals allocate to the displayed orientations of other individuals, and to their own orientations. The accorded weights are components of the heuristic within-the-skin mechanism with which each individual synthesizes heterogeneous orientations. The repetitive automatic activation of this mechanism enables flows of influence in the network. Under this premise, the investigation of influence in networks importantly extends the implications of natural automatic heuristic mechanisms of cognition to the domain of group dynamics.

Models of Power in Exchange Networks

John Skvoretz, University of South Florida, Tampa, FL, USA

© 2015 Elsevier Ltd. All rights reserved.

Abstract

Research into power in exchange networks is based on a large corpus of experimental studies and has spurred the development of many theories to account for experimental outcomes. The types of networks that fall into the domain of these theories are described. How these objects are instantiated in experimental procedures are outlined. The various theories that have been proposed are mentioned but four are set out in detail: power dependence theory, core theory, expected value theory, and network exchange theory. Finally, the results of two recent evaluations of these theories, one empirical and one theoretical, are summarized.

Research on power in exchange networks is unusual in sociology because it formulates relatively clear mathematical models for power in the context of their evaluation through laboratory experiments. In this research, power is measured by the relative earnings from exchange between subjects occupying positions in networks of exchange. Power is relational since the profit from exchange is zero-sum, in the sense that the more profit A earns in exchanges with B, the less profit B earns. However, exchange is mixed motive because both A and B are better off if they exchange, even if one is only marginally better off, than if they do not exchange with each other or with any other person. If A earns reliably more profit in exchange with B than B does with A, A is deemed to have power in the A–B exchanges. Informally, power outcomes fall into three types: strong power outcomes in which A reliably earns much more than B, weak power in which A reliably earns more than B but only a modest amount more, and null or equal power in which A and B earn about the same amount, or more technically, the difference between their earnings is not significantly different from zero.

Formal modeling was evident 40 years ago in the early development of this research field. Emerson (1962: p.31) used network imagery and basic equations relating power and dependence for his "simple theory of power relations." As compared to recent work, Emerson's formal models were crude, even when more fully elaborated several years later (Emerson, 1972) but they set the tone for future research. In part, the nature of the problems demanded mathematical treatment since it was clear from the beginning that A's power in exchange with B was affected by the nature of the interdependencies between the A–B relation and the other exchange relations that A may have and that B may have, and the relations that their partners may have, and so on, as embodied in the overall pattern of connection in the network. Tracing out the path of effects could not simply be left to verbal gymnastics.

The use of experiments to evaluate formal models is also a longstanding feature of this research area beginning with Cook and Emerson (1978) and including Brennan (1981), Cook et al. (1983), Markovsky et al. (1988), Molm (1990), Skvoretz and Willer (1991, 1993), Bienenstock and Bonacich (1993), Lovaglia et al. (1995a), Molm (1997), Lucas et al. (2001), Emmanuelson (2005), and Willer and Emmanuelson (2008). In general, these experiments use social psychology's equivalent of the fruit fly, the undergraduate, as subjects who are placed in relatively small exchange networks and left to bargain with one another over the terms of exchange. In early research, communication was done via paper and pencil and sometimes through face-to-face communication with barriers to prevent some pairs from communicating. Current state of the art in experiments uses workstations connected via local area networks and sophisticated GUI displays to present setting information and in-round details of the back and forth of negotiations.

Theories of power in such networks do not focus on how A's power in exchanges with B depend on differences in personal attributes like bargaining toughness or aggressiveness. Rather the scientific problem is generated by the fact that A, B, and their exchange relation are embedded in a network of such relations and the important questions are (1) to identify the properties of positions in such networks that provide advantage or disadvantage and (2) to uncover the mechanisms by which these properties produce power differences of greater or lesser magnitude. In pursuit of these questions, variation in individual attributes is, for the most part, noise to be statistically controlled and filtered out of the analysis. At the same time, the pursuit of these questions requires data from networks in which relevant properties of the positions occupied by A's and B's vary. These properties capture differences in how positions are connected directly or indirectly to others in the network through direct exchange relations or chains of such relations.

These questions have attracted the attention of many researchers over the past 40 years and there have been many theories or models for power in exchange networks proposed, including power dependence theory (Cook and Emerson, 1978; Cook and Yamagishi, 1992; Buskens and van de Rijt, 2008), Vulnerability theory (Cook et al., 1983; Cook et al., 1986), graph power index or GPI theory (Markovsky et al., 1988; Patton and Willer, 1990; Markovsky et al., 1993), expected value theory (Friedkin, 1992, 1993; Bonacich and Friedkin, 1998), core theory (Bienenstock and Bonacich, 1992, 1993; Bonacich and Bienenstock, 1995, 1997), exchange-resistance theory (Skvoretz and Willer, 1993), reciprocity theory (Skvoretz and Lovaglia, 1995), identity theory (Burke, 1997), and versions of network exchange theory, which include optimal seek theory (Simpson and Willer, 1999; Girard and

Borch, 2003) and, most recently, domain analysis theory (Willer et al., 2012). In a systematic survey of predictions, van de Rijt and van Assen (2008: p. 260) restrict attention to four – core theory, power dependence theory, expected value theory, and network exchange theory – because "no theories have been investigated as much and received as much attention as these theories."

Exchange networks comprise the domain of all these theories. Some basic terms define these entities. Actors refer to occupants of network positions; they may be concretely individuals, teams, organizations, or other collectivities. Negotiated exchange refers to a bilateral agreement that benefits both partners, and in typical experimental setups exchange occurs when there is mutual agreement on the division of a 'profit pool' of points. There are also nonnegotiated forms of exchange defined by the mutual gifts of points to partners. In negotiated exchanges, potential partners can bargain over the division of the pool – the actual procedures for bargaining can differ across experimental setups. In nonnegotiated exchanges, an actor has the option to send a number of points, fixed by experimental design to a partner and no capability to change or 'negotiate' the number of points. The vast majority of empirical studies have focused on negotiated exchange networks. Molm (1990) and Molm et al. (1999) are notable exceptions.

An exchange tie refers to a pair of positions between which an exchange is possible while an exchange network is a set of positions connected by exchange ties. A position in such a network is a location in the overall pattern of connection. Profit pool refers to the total number of points that can be divided in an exchange. Typically, all profit pools are the same size. Experiments are usually organized into sessions or rounds. In negotiated exchange networks, a session is an opportunity for actors to negotiate pool divisions with those to whom they are connected by an exchange tie. In nonnegotiated exchange networks, a session is an opportunity to give points to a partner.

The networks themselves are built up from exchange ties. As noted earlier, critical to the phenomenon of power in these networks is the type of interdependency between and among exchange ties. Classification of exchange ties focus on how exchange in one of an actor's ties impacts exchange in other ties that the actor has. (Clearly, when an actor has only one tie, the distinctions are moot.) Terminology varies somewhat from research program to research program. One type of interdependency, however, is of little interest and that is 'null' interdependency. Two exchange ties have a null connection or interdependence if the completion of exchange in one of them has no consequences for the chance that exchange is completed in the other and vice-versa. These connections are of little interest because the completion of exchange in any one tie is independent from the completion of exchange in any other tie. Thus the 'network' reduces to an independent set of dyadic negotiations subject only to time constraints that may apply if a position has many ties to others and only limited time in which to complete an exchange in each. Therefore, there can be no systematic or structural basis for power in such networks of null interdependence. In terms of early network theorists Holland and Leinhardt (1979), such networks exhibit no interesting structure because what occurs in one dyad is independent of outcomes in any other.

A widely investigated type of interdependence that does have structural consequences of power development is negative or exclusive connection. A pair of exchange ties at a position is negatively or exclusively interdependent, if completing an exchange in one precludes or eliminates the possibility of completing an exchange in the other. More generally, negative connection between two ties means that completing an exchange in one tie decreases the probability of exchange in another. At the extreme, the second exchange is impossible. This extreme occurs in the '1 exchange regime, an experimental protocol that creates networks of negatively connected exchange ties by permitting actors to complete only one exchange per session. The negative or exclusionary interdependence can be more complicated holding among three or more exchange relations through a regime that limits the total number of exchanges that may be completed to less than total number of exchange ties available. In this more complicated case, completion of an exchange in any one tie does not preclude completion of an exchange in any particular other tie, unless it is the last possible exchange to be completed in which case exchange is precluded in all remaining active ties.

Less widely investigated but still of importance structurally is positive or inclusive connection or interdependence. A pair of exchange ties is positively or inclusively connected if the completion of exchange in one increases the probability of exchange in the other. There are several experimental protocols that can realize this type of interdependence. For example, the experiment could stipulate that earnings in one tie can only be converted to actual payoffs if an exchange is completed in the other tie. A related protocol creates positive connection by stipulating what is earned in one tie can then be traded for something of even greater value in a second tie. Again, sets of three or more exchange ties can have more complicated modes of positive or inclusive connection. Furthermore, sets of exchange ties can combine null, negative, and positive connections in various combinations making for a very complex network of interdependencies of exchange ties across positions. In general, however, theory and research focuses on negatively or exclusively connected networks. Szmatka and Willer (1995) and Willer and Skvoretz (1997) are notable exceptions.

Experimental methods for negatively connected networks have some common features. First, subjects are instructed to earn as much as possible for themselves, that is, to approximate the utility maximizing actor of the rational choice theoretical framework. Second, all profit pools that define the possible earnings from exchange are of the same size. In one standard implementation, the full information design, subjects are presented with the overall design of the network clearly indicating which position they occupy and they expect to change positions periodically. The profit pools contain 24 points. Offers, counteroffers, and agreements can be communicated at any time during bargaining sessions of fixed duration. Exchange occurs when partners agree on a division of their pool. Once all agreements that could be made are made or time runs out, the session ends and a subject earns whatever share was agreed upon if they made an exchange or earns 0 points for the round if he or she failed to complete an exchange. Note that failure could be due to time running out before an exchange was made or due to all potential partners completing exchanges with others. In another standard implementation, restricted

information, subjects only know how many partners they have and not the overall design of the network. They do not expect and do not change positions periodically. Profit pools are 30 points. Subjects make one offer per session to each partner, and may increase/decrease by one point (or leave unchanged) the offer in the previous session. Exchange occurs when offers are mutually compatible (with multiple compatible ones eliminated by random selection). Skvoretz and Burkett (1994), Lovaglia et al. (1995a), and Simpson et al. (2011) are three studies that investigate how information differentials may affect the distribution of power.

As van de Rijt and van Assen (2008: p. 260) point out, four theories of power in exchange are the most widely represented in empirical studies: core theory, power dependence theory, expected value theory, and network exchange theory. Each of these may be described in turn.

Core theory applies concepts from cooperative game theory, namely, the concept of the core as a special set of outcomes, to network exchange (Bienenstock and Bonacich, 1992, 1993; Bonacich and Bienenstock, 1995, 1997). Specifically, core theory assumes that when a core set of outcomes exists, it contains all outcomes that will be observed. An outcome, defined as a payoff distribution to each actor, is in the core if it satisfies conditions of individual, coalitional, and collective rationality. Individual rationality is satisfied if each person earns at least as much as he or she could alone. Since that quantity is always 0 by experimental design, the condition is trivially satisfied. Second, coalitional rationality means that each subset of actors should earn in sum at least what they get without the cooperation of actors not in the subset. Finally, collective rationality means that the sum of the earnings in the entire group is as large as possible. Bonacich (1998) shows that there are four types of core solutions for the typical 1-exchange regime: (1) the entire profit pool is allocated to some positions and zero is allocated to all other positions, (2) exactly $^1/_2$ of the pool is allocated to any pair completing an exchange, (3) an infinite number of allocations constitute the core, and (4) the core is empty. He also shows that in the third case, additional considerations can put inequality bounds on the outcomes such that it is possible to infer that some positions should earn no less than $^1/_2$ of the pool size in exchanges.

Power dependence theory assumes that actors evaluate offers from partners in relation to how much they could get in some alternative relation (Cook and Emerson, 1978; Cook and Yamagishi, 1992; Buskens and van de Rijt, 2008). This possible payoff from an alternative partner is the actor's comparison level for exchanges with a focal partner. The difference between the comparison level and the offered terms defines the dependency of the actor on the focal partner for favorable outcomes. Simultaneously, the partners of the actor are conducting the same evaluation of the actor's offers. Terms of exchange are struck at the point that both actors are equally dependent on each other for favorable outcomes, that is, at the point that both are earning in exchange with each other exactly the same number of points more than their respective next best offers. Power dependence theory holds that this logic applies to all but suboptimal exchange ties in a network, where suboptimal ties are ones in which the partners can gain more from other partners at equidependence than from each other and so have no incentive to ever complete an exchange.

Expected value theory proposes that the earnings received from an exchange condition are the likelihood that the exchange will occur and these likelihoods, in turn, determine the probabilities that actors are excluded from exchange (Friedkin, 1992, 1993, 1995; Bonacich and Friedkin, 1998). These probabilities, in turn, influence the terms of exchange that actors will offer one another and so lead to differences in earnings received. Then, in a recursive fashion, the earnings received lead to adjustments in the likelihoods of exchange, which then change the probabilities of being excluded, which finally impact the terms offered and so on until a formally defined convergence criterion is reached. Expected value theory is more similar to power dependence theory than it is to core theory – it produces specific point predictions of power differences in all types of networks, unlike core theory, but, unlike power dependence theory, it adjusts the expectations of value to be received from another source by the probability of receiving such value through exchange.

Network exchange theory, unlike the previous three theories, is the most difficult to summarize because it has had many variants over several decades of development (Markovsky et al., 1988; Patton and Willer, 1990; Markovsky et al., 1993; Skvoretz and Willer, 1993; Skvoretz and Lovaglia, 1995; Lucas et al., 2001). The variant that recent research (Willer and Emmanuelson, 2008) considers the 'best' based on empirical evidence combines graph power index – resistance theory (Lovaglia et al., 1995b) with optimal seek (simplified) theory (Girard and Borch, 2003). The basic idea of this theory is to first identify substructures of an exchange network that are strong power, equal power, or weak power substructures and the breaks between such substructures that will occur because actors have no incentive to seek exchange with one another even though they are connected by an exchange relation. In strong power substructures, actors in one set of positions (labeled I for included always) are predicted to earn the maximum share of a pool and actors in the other set of positions (labeled E for excludable) are predicted to earn the minimum share. In equal power components, all nodes are I or all are E and have the same number of connections and so the prediction is that, of the net of exogenous individual factors, each actor will earn 50% of any pool. Calculation of shares in the weak power components is more complicated, taking into account differences between positions in their likelihood of being included in exchange and how such a difference affects the best and worst they can expect from an exchange.

Two recent evaluations of these theories exist. Willer and Emmanuelson (2008) use data from seven 'weak power' networks to test the predictions from these four theories and six others. Weak power networks are selected for the basic reason that predictions of all theories for the other types are indistinguishable, that is, all theories propose that in strong power networks advantaged positions will earn nearly all the available points in a pool and all theories propose that in equal power networks, pools will be split evenly. It is only in the case of weak power networks that the theories make distinguishably different predictions. As noted above, they find that the best fit to data from these networks is provided by a version of network exchange theory.

The second evaluation by van de Rijt and van Assen (2008) is not an empirical evaluation but an evaluation of logical aspects of the theories against six desiderata: predictions should be invariant under scalar multiplication of the size of the profit pool; predictions should be identical for positions that are automorphically equivalent, distinguishable from one another only by label (symmetry); predictions should exhibit outcome stability, that is, the sum of predicted payoffs for any pair of connected actors is always greater than the sum attainable by exchanging themselves; predictions should be sensitive to link deletion in a downward direction only, that is, if the link between A and B is deleted, their predicted payoffs are less than or equal to their predicted payoffs in the network with the link restored; predictions should exit, that is, there should be at least one payoff vector predicted; and, sixth, the prediction should be unique. None of the four theories has all six desirable properties. In two cases, expected value theory for the existence property and network exchange theory for the symmetry property, van de Rijt and van Assen are unable to determine whether or not the theory satisfies the criterion. Their evaluation concludes that no one theory is superior to the others and so any nonempirical choice among theories would be based on the relative value placed by a theorist on each of the six desiderata. For instance, an advocate of network exchange theory could argue that its violation of the first criterion, because it predicts a disadvantaged actor will get 4.2% of a 24-point pool but 20% of a 5-point pool (getting the minimum possible in both cases), is not a very serious error, but rather reflects better than the other alternatives – the constraints of any experimental protocol – namely, that even the most severely disadvantaged must get something to motivate completion of an exchange. Or an advocate of core theory could argue that its violation of the symmetry criterion with respect to a particular payoff vector is misleading since in the case cited, it predicts a set of vectors in which automorphically equivalent actors occupy identical positions when all imputations are considered and of which the particular vector is just one possible outcome.

These two studies evaluate theories for power in negotiated exchange networks. Power in nonnegotiated or reciprocal exchange networks has received limited attention. In these networks, an exchange relation is defined by the opportunity for an actor to give unilaterally a fixed number of points to his or her partner. If the actor has more than one partner, only one can be selected on a round, thereby, creating a negative connection between his or her exchange ties – the more often the actor gives in one relation, the less often the actor gives in the others. Available evidence provided by Molm et al. (1999) suggests reciprocal exchange produces smaller power differentials in otherwise similar networks but the same pattern of difference across different types of networks – namely, greater earnings differences in strong power networks than in weak power networks.

Summary

A general theory of power in networks, even one limited to networks of negative connection, remains an elusive goal and not for lack of effort. Over the years, various proposals have been made. Even the more successful have not been built in a dynamic modeling framework – the general pattern is to identify some measure of position sensitive to the location of that position in the overall pattern of connection and postulate that a difference in this measure between two positions connected by an exchange relation will produce a greater or lesser difference in the earnings of actors in these positions from exchange. (This generalization includes proposals, like expected value theory, that have an iterative component in which values expected from exchange condition the probabilities of exchange, which in turn modify the values until some convergence is reached.) The goal is to understand how structure (network location) shapes process (negotiation to agreement) to produce structural effects on outcomes (differential earnings), but without an explicit representation of the process it is doubtful that the goal can be achieved. Even if a proposal, such as the most recent one deemed best by Willer and Emmanuelson (2008), is generally agreed to be descriptively adequate, the deeper question of explanatory adequacy – why a particular representation of the problem provides empirically satisfactory fits – requires delving into the details of process, a multiagent search through a space of possible deals constrained by the complex interdependencies among points deriving from the underlying network of exchange connections.

Abstract

This article introduces the definition of moderator variable in statistical analysis and how moderation is different from mediation and interaction. It also discusses potential problems with the interpretation of the moderation effect that arise in observational studies, as well as their relationship with significance testing and variable transformations.

Typically theoretical models in the behavioral sciences posit that independent variables affect dependent variables. A moderator variable is a variable, which is thought to temper or modulate the magnitude of the effect of an independent variable on a dependent one. Moderators may be characteristics of people or characteristics of situations. In either case, they affect the magnitude of the relationship between an independent variable and a dependent one. Moderation implies an interaction between the independent variable and the moderator. Analytic procedures using both analysis of variance and, more generally, multiple regression, permit the testing of such interactions. Tests of interactions with measured, as opposed to manipulated variables, may not have high statistical power. Complications also arise due to the typically arbitrary metrics of many dependent variables. Nonlinear scale transformations can eliminate interactions and affect conclusions about the presence or absence of moderation.

A moderator variable is a variable, which is thought to temper or modulate the magnitude of the effect of an independent variable on a dependent one. Conceptually, it is important to differentiate between a moderator and a mediator. A moderator is a variable that affects the magnitude of the relationship between the independent and dependent variables. It identifies the conditions under which, or the type of participant for whom, the effect is likely to be particularly large or particularly small. A mediator is a variable that describes the process that is responsible for the effect of the independent variable on the dependent one. It is a variable that is affected by the independent variable and in turn affects the dependent one, thus being responsible for the effect. (*See* Mediating Variable; also Baron and Kenny, 1986; Muller et al., 2005; MacKinnon et al., 2007; Fairchild and MacKinnon, 2009; Pearl, 2010, 2012.)

Examples of Hypotheses Involving Moderation

Hypotheses about moderation are ubiquitous in the social and behavioral sciences. The following examples, taken from a variety of fields, provide illustrations. Each example consists of two sentences. The first hypothesizes an effect of an independent variable on a dependent one. The second sentence identifies a hypothesized moderator.

1. Level of education attained affects lifelong earnings. This relationship is less strong for females than it is for males.
2. Stressful life events tend to produce psychological problems. These effects are lessened if one has an extensive social support network.
3. Some forms of instruction lead to better retention than others. These effects are larger among more able students.
4. Exercise has pronounced health benefits. These benefits are more pronounced among older people.

Note in these examples that moderator variables can take on a variety of forms. They can refer to characteristics of the participants in the research (i.e., their gender, ability, or age); equally plausibly they may characterize the situations or environments which moderate the relationship between the independent and dependent variables. Additionally, their scale of measurement may be nominal (e.g., gender) or may vary more or less continuously (e.g., ability levels).

Conceptual and Analytic Issues in Testing Moderation

To say that one variable moderates the effect of another is equivalent to saying that there is a statistical interaction between the two variables. Accordingly, moderation implies interaction, although not all interactions involve moderating variables. The distinction is as follows: moderation means that there is a main effect of the independent variable plus an interaction between the independent variable and the moderator. Overall there is an effect of the independent variable, but the magnitude of that effect depends on the moderator. An interaction, more generally, makes no claims about the presence or absence of the main effect of the independent variable. It simply indicates that the effect of one variable depends on another.

Because moderation implies a main effect of the independent variable plus an interaction of that variable with the moderator, typically interactions in the presence of moderators are not what are called crossover or disordinal interactions. That is, from one level of the moderator to others, the effect of the independent variable varies in magnitude but not in direction. To illustrate, consider the first of the examples given above, that gender moderates the relationship between educational attainment and lifetime earnings. For both genders, there is presumably a positive effect of educational attainment on earnings, but that positive effect is less strong among females than among males. For no level of the moderator does the relationship between educational attainment and earnings reverse.

Because moderation implies an interaction, it is necessary that the moderator and the independent variable be at least partially independent of each other. Ideally, the two variables would be fully crossed as in an experimental design where both variables are manipulated independently of each other. More typically, while the independent variable may be manipulated, the moderator may be a measured variable that varies more or less continuously. Again, however, to assess moderation it is important to insure that observations from all levels of the moderator occur at every level of the independent variable.

Analytically, moderation is typically assessed via either analysis of variance or multiple regression procedures, with the choice between the procedures traditionally depending on the scale of measurement of the independent and moderator variables. Two effects are of interest. First, the overall main effect of the independent variable is expected. Second, moderation of that effect implies that the interaction between the independent variable and the moderator is statistically significant. The use of analysis of variance to assess moderation is perfectly appropriate when both the independent variable and the moderator are measured on a nominal scale, with a few discrete levels of each variable. With moderators that vary more or less continuously, regression procedures are more appropriate, since substantial loss of power can occur if continuously varying moderators are broken up into discrete levels (e.g., using a median split) to accommodate them in analysis of variance. In general, multiple regression can be used to assess moderation, regardless of whether independent and moderator variables are scaled discretely or more or less continuously. In the case of discrete or nominal scaling, one simply must compute dummy-coded or contrast-coded variables to be included as predictors. The general model involves including as predictors the independent variable, the moderator variable, and a variable that is the product of the two. The test of the product variable, controlling for the two components of that product, provides a test of the statistical interaction (Cohen, 1978). In this analysis, one must be cautious in interpreting the coefficients (and their associated statistical tests) of the component variables (i.e., the independent and moderator variables in a model that includes their product). Unless these variables have been centered on their means (and the product computed from those centered variables), their coefficients will not be readily interpretable as the average or main effect of each variable (Aiken and West, 1991; Judd and McClelland, 1989; Henseler and Fassott, 2010; Aguinis, 2004).

In some situations, the independent variable is likely to vary within units rather than between them (Judd et al., 2001). For instance, the effects of mood as an independent variable may be assessed by naturally occurring variations in mood within individuals over time. In these cases, traditional tests of statistical significance of both the main effects of the independent variable and its interaction with a moderator are likely to be biased unless dependencies in the data are appropriately handled. Repeated measures analysis of variance and, more generally, hierarchical linear models can be used to assess moderation in these sorts of designs.

Tests of moderation with naturally varying, as opposed to manipulated, independent, and moderator variables are likely to have relatively low statistical power. Compared to the experimental situation where both variables are manipulated, there is likely to be less variation in the independent and moderator variables in the case where these variables are measured as they naturally occur. As a result the residual variation in their product is likely to be particularly small compared with the situation where both variables are manipulated. Tests of moderation (and interaction more generally) might then be most powerfully conducted by selecting units with relatively extreme values on the two variables (McClelland and Judd, 1993).

Interpretive Ambiguities

As the examples in Section Examples of Hypotheses Involving Moderation illustrated, moderation hypotheses are ubiquitous in the social and behavioral sciences and analytic procedures for testing interactions, as described in the previous paragraphs, are relatively well worked out. However, interpretive difficulties can arise in describing moderation unless strong assumptions can be made about the metric of the dependent variable in any analysis. Nonlinear transformations of the dependent variable may eliminate interactions, especially when those interactions involve moderation of a main effect of an independent variable, rather than a crossover interaction.

Consider a simple example from cognitive psychology. Participants are timed while identifying letter strings as words or not (a lexical decision task). Words are either preceded by a semantically related prime or not. The main hypothesis is that primes should decrease the latency of the lexical response. Target words vary in their familiarity or frequency in the language. The effect of primes is expected to be moderated by word familiarity, such that prime effects are larger for less familiar target words. Hypothetical latency means (in seconds) are given in the left-hand portion of **Table 1**. Evidence is found for moderation: the prime versus no prime difference is more than twice as large for unfamiliar words (0.033 s) as it is for familiar ones (0.015 s). But now consider what happens if we convert the means to represent speed of response (rather than its latency) by taking the inverse of the latencies. In the speed metric, there is absolutely no evidence for moderation due to familiarity.

Which is the correct analysis? What conclusion about moderation is correct? Unfortunately, since there is no way to define the more appropriate response metric, there is no way to answer this question. The lesson is that many interactions in the social and behavioral sciences, where the metrics of the variables are somewhat arbitrary, disappear under nonlinear scale transformations. This is particularly likely to be the case when interactions are not crossover, as in the case of moderation.

Table 1 Means illustrating scale transformation that eliminates moderation

	Latency metric (tenths of seconds)		*Speed metric (inverse transformation)*	
	No prime	*Prime*	*No prime*	*Prime*
Familiar	0.556	0.541	0.0180	0.0185
Unfamiliar	0.833	0.800	0.0120	0.0125

To be confident about the presence of moderation, given arbitrarily defined metrics of most dependent variables in the social and behavioral sciences, analyses should be conducted using a variety of different metrics. If interactions prove to be significant under a variety of different nonlinear transformations, then confidence concerning the presence of moderation increases.

Modern Management: Origins and Development

John-Christopher Spender, Kozminski University, Warszawa, Poland

Abstract

Accounts of the origins and development of management have two deficiencies: (1) they fail to distinguish managing a business from other types of managing and (2) they are more often histories of writing about management than of doing it. Explaining management requires attention to the nature of the thing being managed – the firm. The history must hinge on specific aspects that distinguish today's management from that of former times; and various have been advanced – scale, technology, and globalization. Yet all were evident long ago and miss what is modern about modern management. This article treats the modernness of the mode of business administration as key to understanding the modern firm. Following Weber the bureaucratic mode is tempting but once we accept Knightian uncertainty, bureaucratic theory cannot be an adequate guide to today's managerial practice. Modern firms align employees' judgment rather than their blind obedience by providing them with a corporate citizenship that echoes but differs from that provided earlier by guilds. The historical origins and development of managing are of this transition.

The Chronology of Management

History stands on time, so management's history requires a time-contingent definition of management with moments or periods in which management changed markedly from managing past to managing present. If managing has been the same since time immemorial it has no history. If it is simply 'getting things done through other people,' it has a long history indeed, but with no clear transitions to support a historical analysis. The classic works on the history of management or of management thought presume the world is always changing and lay out a sequence of periods marked by different managerial focus (Witzel, 2011). Unfortunately too often this is a history of academic writing about management rather than a history of doing it. Many of the transitions are arbitrary and assigned to a particular time without adequate evidence, such as the oft-remarked transition from the 'inhumanity' of scientific management to the Mayo-inspired human relations movement. A glance at eighteenth- and nineteenth-century business texts shows considerable concern for human beings, albeit not in today's language (Freedley, 1879). At the same time these histories make little of the distinction between managing generally – e.g., in government, military, or the Church – versus managing firms, now more or less implicit in the term 'management.' Management schools are not much concerned with the public sector.

Even as we think of managing as something quintessentially modern and to do with firms we have difficulty determining the characteristic that marks this modernity and when it began. Many, influenced by Alfred Chandler's work, argue scale marks modern management's emergence, the rise of large corporations toward the end of the nineteenth century, especially in the US but also in Europe and Japan. Unfortunately scale does not provide a sound chronology. As economic historians know, large-scale economic organizations, such as plantations, potteries, or naval shipyards (de Vries and van der Woude, 1997) were widespread in the eighteenth century and evident many centuries before. Plus many criticize how Chandler prioritized managers' structuring decisions over responding to contextual changes (Rosen, 2013). Other 'modernists' stand on technology, seeing modern management as marked by the technological changes that precipitated the Industrial Revolution – as illustrated in Denis Diderot and Jean d'Alembert's *Encyclopédie* of 1751. Yet technological change is not a secure criterion either. We see the arrival of 'big data,' a century after Chandler's explanatory moment. If this is crucial, today's senior managers, nurtured in an earlier era, should be ill equipped to manage today's IT-penetrated firms. In fact they simply employ IT specialists to handle the new technology, just as their forebears managed coal mines from the surface or colonial trade from London through agents or employees. Hiring employees and agents with appropriate skills shields managers from external change. Others cite Fordism and scientific management as useful ways of distinguishing modern management from previous ways of 'getting things done through others.' Yet mass production goes back far beyond the Springfield rifle to, for instance, the mass production of ships and tackles in the fifteenth-century Venetian Arsenal.

A more persuasive chronology emerges if we think modern management is distinguished by its quantitative methods, the dominance of 'the numbers.' A growing literature argues modern management (and indeed modern society) is marked, even caused, by the expanding use of measures and statistics (Porter, 1995). Max Weber's work on the spread of rationalism is influential (Weber, 2003). Likewise Frederick Taylor's contributions to managerial accounting impacted twentieth-century management practice more than his infamous 'time and motion' studies. Accounting goes back beyond Roman times. William Petty (1623–87) used statistics while surveying the Irish territories occupied by Cromwell's armies, and to calculate taxes and the nation's wealth. Post-World War II advances extended accounting and measurement, but merely describe aspects of modern managing without defining it. In practice accountants, statisticians, and quantitative analysts are 'staff' employed to advise management as a practice that always calls for judgment beyond 'the numbers.' In the military tradition, Fayol distinguished 'line' from 'staff' and we can likewise distinguish analysis from the exercise of managerial judgment when the numbers are not conclusive, when choices remain after the analysis is complete. Note that when managers

employ others having the professional skills to shield them from changes in technology, accounting standards, laws, regulations, and so on they exercise judgment; indeed Frank Knight regarded choosing subordinates as the severest test of a manager's judgment (Knight, 1965).

For some this 'judgment lying beyond analysis' is the essence of managerial practice and thus of a viable chronology, suggesting today's professionalized forms of managerial judgment can be contrasted against the arbitrary or prescientific judgment of past times. As Khurana's analysis of the history of US management education revealed, at the end of the nineteenth century there were widespread moves around the world, to develop a 'science of managing' and establish management as a profession (Khurana, 2007; Spender, 2005). The history of engineering, for example, is of increasing professionalism based on growing scientific knowledge and practical expertise. Unfortunately management meets few of the criteria for a profession; there is no qualification or policing of entry or exit; no institutional body to judge members' conduct and, most importantly, no certified body of professional knowledge against which to measure training, qualification, conduct, growth, or change. Though many speak loosely of management as a profession, it is not like any of the 'real professions' – medicine, engineering, or law. While management has generated many professionalization initiatives, none have had great impact on managerial practice. After a century of aspiration and claim, plus the 1959 Foundation Reports, business schools have yet to develop the science necessary to underpin a profession and, in consequence, their role is less to provide professional training than to help students into the hiring pipeline. Ironically, many of the business heroes of the early twenty-first century, such as Bill Gates, Mark Zuckerberg, Steve Jobs, Richard Branson, Marissa Mayer, and Bernie Ecclestone, lack 'professional training.'

What can be said if we have no viable chronology of managing, no clear separation between management past, present, and, by implication, future? Errors here are to think the history of management is (1) of a rational practice or body of general laws that can be separated from the specifics of the historical context in which it is of value or (2) from the idiosyncratic judgment of the managerial actor. When looking for its history it is not useful to think of managing as a form of social physics, a science to be applied objectively in fully known situations, for we have made no such progress. Rather, the search for a history must be in the complementary German historical tradition, of treating managing as the application of a specific person's judgment in a specific situation to be judged good or bad in terms of the judgments being applied to the situation. Instead of a chronology of managerial practice that advances from irrational to rational, or from prescientific to professional, or providing a sequence of academic writing genres, we must create a chronology of managerial situations and actors, and of managers' judgments as these draw in their agency, their 'judgments beyond their analyses.'

An ancillary problem is that if every collision of actor and situation is unique there is little to be said. Historians, eschewing general laws, presume situations and actors are not entirely unique, that insights garnered from examining judgments in one situation can illuminate its application in others even as they are not determining. For example, one change might be that the nineteenth-century notion of standardization that drove the 'American system of manufacturing' could be widely applied to administrative work as well, setting the stage for bureaucratic planning and the training to support it. Though many writers presume firms are rationally designed and managed bureaucracies, itself an opinion with a history, few managers feel bureaucratic theory an adequate description of their practice, more an aspect or possible mode of managing. We might likewise point to the 'invention' of the limited liability corporate form in the seventeenth century. It clearly changed the context of managerial practice from the earlier partnership form, given it radically shifted financial risk. No doubt the firm's legal form indicates constraints to managing and many of today's forms such as S corporations or 501(c)(3) seem 'modern' in comparison to partnerships. Managing a family business or a partnership is not the same as managing a multinational or not-for-profit. Managing a global enterprise, especially in the Internet Age, is different from managing in the English East India Company's early years (Keay, 2010). In short, the chronology we seek is one of the changing contexts in which managers do whatever they do, for managing is not the exercise of a universal rationality; it calls for situation-specific judgments. Being contingent, it has a history that can be told in terms of the changing contexts of its practice.

The Changing Contexts of Management Practice

Perhaps the principal change in the context of managing over the last few centuries – even more than the changes in IT and other technologies – is the erosion of business's monopoly powers, in part because of the loss of government grants and charters and the growth of government intervention with antitrust legislation and regulations, and in part because of globalization, competition, and greater consumer choice. Without citing much historical evidence, many academics pronounce business has become 'hypercompetitive.' We also hear that managers' power within firms has changed from eighteenth-century Dickensian absolutism to the bargaining situation exemplified, perhaps, in German *Mittlestand* firms. Even if these changes have indeed occurred it does not follow that they have made managing more difficult, perhaps the opposite. As the economy develops an 'invisible hand' appears in the background, the *deus ex machina* in the business drama that takes charge when markets are 'efficient.' As information flows improve and transaction costs drop 'efficient markets' emerge, an ordering that is not the artifact of individuals, managers, or the state. Many argue market forces should be our socio-economy's dominating mode of ordering, buttressing our democratic politics and our ethics of independence. Management's role then narrows onto reading and following, as rationally as possible, markets they neither engineer nor command. Social and political power is downplayed and becomes suspect as 'interference' in efficient markets. So one history of managing is of moving our economic affairs into increasingly efficient markets in which rationality dominates judgment.

But managing a business is never just about markets. Adam Smith knew their importance but he also saw an enterprise as a context in which entrepreneurs and capital come together

with others (labor) in a place of work (land). His intuitions about market behavior were formalized into Marshall's 'scissors,' the familiar crossing of demand and supply curves, and this led on to the microeconomists' definition of managing as price and output setting. But ignoring market imperfections, microeconomists are still not able to address the creation of economic value. Smith thought differently and was not only interested in markets. Following Petty, he implied managers should focus on the learning and tools generated within the enterprise, for that ultimately drove the nation's wealth. If some believe managing under perfect competition was Adam Smith's hope; we know Hobbes's views were very different – order comes from an exercise of power. Managing is not only analysis; it is also an exercise of power and the creation of an economic order that does not emerge on its own. Consequently management practice lies in two contexts: (1) directing firms interacting through competitive markets and (2) exercising power over individuals (employees) so as to create order, predictability, and economic value within firms. Thus it has two histories – one oriented toward dealing with changes in markets, the other toward ordering within the firm's boundaries – and, of course, a history of how these two are brought together in practice. While managers have a degree of power in both contexts, the relevant modes of power and integration differ. Loosely speaking, efficient markets deny managers any significant 'market power'; but if markets were efficient they would not have much of a history. Real markets are such that managers must deal with their social and economic imperfections. They have a history because these imperfections change. The histories of commercial and financial markets are rich and fascinating, especially their increasing scope, articulation, and sophistication since the Dutch Republic, though it is important to appreciate most of the financial instruments necessary to today's capitalism were developed before the time of the Florentine bankers.

The markets for products and for labor are structured and paced differently. Labor law and regulation has supplemented workplace activism and unions. Managing has been changed by the redistribution of power within the firm and the development of more participative modes of control. Many regard this as the cutting edge of management change and thus to its history. But this presumes the nature of the firm is less problematic than it is. Today managing is about firms – but what are these? The remainder of this article focuses on the firm itself and its particular history. To anticipate its conclusion, we argue for a historical connection between the growth of the Dutch Republic – dubbed the 'First Modern Economy' – and the changes that demarcate the modern firm – because they transformed its creation. Setting up and sustaining the firm is management's preeminent task so changes here can be made the basis of a history of managing. Modern management, we argue, was 'invented' in the Netherlands around the middle of the sixteenth century. In spite of many later adaptations, driven by the changes in technology, globalization, social norms, corporate law, regulation, or market forces noted above, managing exhibits a core characteristic – its mode of coordinating those employees the firm relies on if it is to adapt and persist in an uncertain and changing world.

Theories of the Firm

The term 'firm' comes from the medieval Italian '*firma*,' the signature that committed partners to a business arrangement or obligation. A modern firm is more than a signature – and here begins the puzzle. As Ronald Coase pointed out, we have no 'theory of the firm' to underpin our distinction between firms, individuals, and markets and, thereby, our notions of managing within the firm (Coase, 1991). What is a firm? Why do they exist? What is their history? Legal scholars have been debating these matters for centuries; even the Roman law on which modern corporate law is based was ambiguous. Today legal scholars see two possibilities; that the firm is (1) an 'unnatural person' with some of the rights citizens have to own property, to sue and be sued, and to contract or (2) it is a managed aggregation of people and assets (Veldman and Parker, 2012). The first frames managing as dealing with markets, the second as dealing with internal matters.

A viable theory of the firm would define or at least clarify this, and so make a history of managing firms possible. Organization theorists and microeconomists have a handful of notions, though the most accepted derive from Weber's theory of bureaucracy, driven by rational choice. The firm is defined as a machinelike apparatus of linked work-roles designed to achieve specified goals. It follows that managing embraces selecting objectives, designing roles, hiring into them, resourcing the activity therein, instructing the work, measuring it, and so on. In 1937, Gulick labeled this analysis POSDCORB – planning, organizing, staffing, directing, coordinating, reporting, and budgeting. Other noneconomic theories of the firm were gathered in Morgan's *Images of Organization*; mechanism, organism, brain, culture, political system, psychic prison, flux, and domination (Morgan, 1997). Each indicates a distinct notion of managing and each has a history. Note management's role varies from considerable to trivial, great in the case of design and control versus marginal when the manager is merely the instrument of the firm's self-organizing process. Just as the invisible hand appears to make managing across markets no more than reading the market's facts, so management within the firm becomes less relevant if the firm is self-organizing. Managers, of course, presume their importance to the firm and its activities, one reason why design and control is their favored metaphor; the history of managing cannot be of their unimportance! Note Morgan's metaphors fall into two classes, focused on managing resources or on managing people. One of the charges against scientific management is that it proposed people were no more than tangible economic resources, so drawing them into mechanistic models.

Paralleling Morgan's metaphors are a handful of microeconomic models of the firm; transaction cost analysis, principal-agent theory, nexus of contracts, property rights, team production, etc. (Spender, 2014). Again these fall into two classes, focused on resources (and prices) or on people (behavior), and they carry implications for managing. The microeconomist's emphasis is on Coase's questions: Why do firms exist? What are their boundaries, where they are? Why are their internal arrangements as they are? Why is their performance so varied? Inasmuch as managing is about 'going beyond analysis,' it is about answering these questions about firms and managing them that economic theory cannot.

Transaction costs economists argue firms exist because they can achieve production costs lower than the prevailing market prices, the make or buy decision in new terminology. But managers must create the lower cost regime before the make or buy decision can be evaluated. Principal-agent economists argue firms exist because they provide principals with a means of controlling agents through incentives and monitoring. Again, managers must create regimes that control divergent interests and knowledge. Perhaps firms exist as a nexus of management-initiated contracts between the firm and its providers and consumers, or because they can hold and protect property rights, or provide a legally structured entity to hold the undistributed results of team production, all management tasks. Douglass North also argued institutions can be understood as responses to social uncertainties. Because a society's uncertainties are contingent on their historical context – there being no overarching theory of social uncertainties – the meaning and nature of the resulting institution lies in the context's history, not in any general principles. Without a 'theory of the context' management's responses cannot be comprehended separately from the specifics of their context; so managing is 'indexical' rather than generic and a history of managing based on imperfections would be hopelessly fragmented.

Looking inwards at the modes of power used to construct and sustain firms suggests a greater degree of generality. Sociologists see three fundamental modes of power: calculation, coercion, and culture. Markets are largely coordinated by calculation. Firms are nonmarkets precisely because they are domains of power, not calculation. Thus the long-term history of managing may be of socioeconomies moving away from coercion (feudal) as the dominant mode of creating social order and toward, first, more efficient markets, and when they are not available, to noncoercive 'cultural' modes of coordination. Coercion is common, of course, and has a history as long as society itself. It remains a puzzle for management theorists; Do threats discourage employees from contributing their judgment? The modern assumption is 'yes,' so culture management lies at the heart of contemporary analyses of managing. Within their firm, managers create and institutionalize a culture of purposive conformance (alignment) that is accepted by those involved as 'managerial authority.' As a voluntaristic order lying between the individual actor and social structures such as the state, a firm's culture implies a collective consciousness or shared sense of objective that shapes the way the firm's individuals dispose their energies and agency toward the firm's objectives (Spender, 2014).

The Modern Firm

Modern management reflects what is modern about our era, especially the need to persuade rather than coerce skillful and politically enfranchised citizens into accepting the entrepreneurs' judgments. The firm is a domain in which employees are persuaded into alignment with the entrepreneur's goals. How does this work? It is generally accepted that modernity began in Florence, initiating the fourteenth-century Renaissance; its principal characteristics being (1) the spread of scientific thinking, objectivity, communication, and empirical methods and (2) the rise of individualism, self-awareness, and freedom from premodern forms of social order (primarily feudal and/or religious). Others argue the plague of 1348 (Black Death) greatly reduced worker populations and precipitated new economic relationships. Citizens acquired rights to buy and sell as they chose, and eventually to establish their own value-creating activities, both economic and artistic, breaking free of feudal and institutional arrangements such as guilds that previously gripped the economy. The bans on assembly, itself regarded as a threat to feudal leaders or the state, were reduced, legitimating individual 'projectors' or 'master adventurers' shaping the economic activity of others. Their freedom to set economic goals was complemented by the evolution of capital markets and corresponding legal and financial instruments, such as rights of incorporation. Entrepreneurs could form entities that could absorb and apply the capital of others. The political, legal, and religious upheavals across Europe also freed many individuals to travel beyond the towns and villages in which they were nurtured, leading to viable labor markets.

The preconditions for an explosion of economic activity were in place in the sixteenth-century Netherlands; religious freedom after the revolt and repulse of the Spanish occupiers, a good supply of labor, skilled immigrants of every variety fleeing religious persecution all over Europe, educational facilities that led to the population becoming the world's most literate. There were substantial technological advances in windmills, textiles, pumps, fish-salting, and intensive agriculture. There was the *waterschap* or *hoogheemraadschap* local democratic political tradition born of the collaboration necessary to create and sustain the dykes and polders. Export trade depended on ships, and the Dutch mastered both designs and methods of production to produce the most economic crafts (*fluyts*). Obviously these preconditions did not cause the evolution of the modern firm, but they comprised a singularly fruitful context for those striving for better socioeconomic arrangements than those of the previous era. It is difficult for us to appreciate how these people thought about economic activity for we are children of a rationalist age (Lecky, 1910). We find the metaphor of the mechanical firm completely acceptable. But to suggest the Renaissance and Enlightenment movements helped an already comprehended economic rationalism emerge from under the crushing weight of feudal and religious ideology is to deny the history of these changes. This is 'Whig history,' a story of how society overcomes impediments to achieve its present perfection. In practice, the economic potential of the division of labor and efficient markets were not self-evident to those engaged in commerce; nor were they knowingly suppressed by those whose interests would be harmed. When Smith was writing, following the work of Petty and the French economists, he was exploring the political and economic implications of then radically new ideas.

Not assuming everything is progressing toward perfection, non-Whig historians work as best as they can from what they know of the past and thence into the present, identifying the phases of change. Likewise we have no crystal ball to tell us how managing might change in the future when, for instance, we might be under constant surveillance. The Netherlanders showed how acculturation and persuasion characterize today's modern firm – in contrast to the coercive and feudal modes of

power that characterized the previous era's manufactories. Understanding that the presence of uncertainty makes judgment necessary to all practice, it also means employees cannot be persuaded by rational argument alone for neither they nor their managers can foresee the consequences of any particular instruction. Note that Coase suggested the nature of the firm sprang from the 'supersession of the price mechanism,' and the employees' willingness to obey the direction of managers 'within certain limits'; the first makes monetary incentives problematic, the second shifts attention onto the processes managers use as they persuade others to do their bidding.

This opens up many questions about firms and managing, but even without resolving these, history provides suggestions about how the modern firm emerged. While responding to changes in technology, finance, and trading will always be important, managing the modern firm is defined by this novel – for the 1550s – mode of administration, cultural rather than either coercive or familial. As Weber noted, economic expansion was limited until entrepreneurs found ways of acquiring human capital beyond the limits of the family, paralleling Penrose's insight that a firm's growth is limited by the rate at which its 'management team' can learn (Penrose, 1995). Crucially, the implication was that employees must give up part of the citizenship rights into which they were newly enfranchised. Thus the modern firm is not an inhuman machine but, more importantly, it offers an alternative mode of citizenship – not inevitably welcomed, as in Whyte's *The Organization Man* (Whyte, 1956). Again Coase's suggestions are revealing. He implied the existence of a 'special class that directs the activities of others' and, parenthetically, of 'those who might prefer to work under another's direction.' The result is an embedded contrast of master and servant or leaders and led. Its ethical and political implications, interesting as they are, do not explain why those who had recently achieved citizenship would voluntarily lessen those rights by moving into a firm's field of power. To argue this is for economic reasons (personal gain) denies Coase's discussion of the frictions or costs of all economic activity (transactions costs). A firm cannot survive if its employees earn precisely what they contribute – even allowing for a just return to capital. Thus as Veblen argued, firms exist because the rewards to investors and employees are less than the value of their contributions (Veblen, 1965). How come this paradox became so widely institutionalized and remains uncontested? This is management's history.

The Guilds

While the Dutch Republic advanced freedom of religion and the rule of law, enhancing political citizenship in ways that were subsequently articulated into the US Bill of Rights and Constitution, the variations on citizenship were more complex than they seem today. Slavery and bondage proliferated (Steinfeld, 1991). Apprenticeship was common. Women's rights differed from men's. Guild membership was especially important to the evolving notion of the commercial firm. Guilds had existed since Roman times but became popular throughout Europe as economic activity picked up in medieval times. Adam Smith criticized them for restraining economic development in ways that anticipated Taylor's distaste for unions. The guilds' eventual decline mirrors the growth of firms as alternative modes of economic organization. We can probe the nature of the firm by considering features of guild life no longer present today. But again, our current modes of economic thought and ideology of rationalism may cloud our sense of why guilds existed. They were deeply intertwined with commerce but were not rational-legal in Weber's sense. The argument they arose to protect craftsmen from competition or for purely economic reasons is to project our thinking backwards into those times. Likewise evidence they resisted technological and legal changes that would improve economic efficiency is balanced by evidence that they often pursued explicitly economic ends. Guilds were clearly involved in managing a trade's intellectual capital by restricting both sharing among members and the rights of nonmembers to practice the craft or enter the trade. But this does not get to the heart of their nature.

There were many reasons why people wanted to become guild members (Epstein and Prak, 2008; Kieser, 1989; Lucassen and Prak, 1998). The guilds' primary *raison d'être* was not protectionism, it was to provide members with social and economic identity, a reputation, just as professionals claim today when identifying as engineers, academics, or whatever, taking their individualism for granted. Sixteenth-century people's identity was more deeply grounded in relationships – family lineage, feudal belonging – and guild membership. The nakedness of today's individualism would have been terrifying to all but the most radical thinkers (and believers). Plus while cash wages were increasingly displacing 'payment in kind,' medieval economic activity was tied up with creditworthiness – to reassure landlords, victuallers, and tailors – and those who supplied artisans with their factors of production; as credit and working capital does today. Amid the Dutch Republic's turbulence an immigrant's work would be unvalidated. Guilds accredited it and made the work tradable, but only after the novitiate went through the guild's entry process and committed to its quality and work policing. Guilds provided care for sick and unemployed members and families, making membership a long-term obligation. Guilds similarly established traders' credentials, for letter of introduction were essential for nonfamily members. Given the times, most guilds were allied with religious organizations, deploying religious ideas to enhance reputations, often becoming religious schools. Guild membership was everything, offering an economic and socially viable citizenship that differed markedly from the problematic social condition of nonmembers.

Guilds provided a citizenship that predated national citizenship and prefigured 'corporate citizenship' today, the modified state of sociopolitical identity Coase noted. The essence of sixteenth-century Dutch managing lay in creating, exploiting, and sustaining a new kind of citizenship, different from that the guilds offered (Sison, 2011). Employment law is such that the nature and boundaries of corporate citizenship remain far from clear today, in part because of the complexities but also because all law is a 'work-in-progress.' Today's employees sign open-ended or 'incomplete' contracts that leave management considerable latitude in determining the employee's eventual duties. Employment today is 'at will' and the fact that employees do not have to take oaths as guild

members did – but as military and religious participants still do – implies a radically more fluid relationship. There are no laws to force an employee to contribute her/his labor. Thus having abandoned the coercive tools available (still) to military and religious organizations, the modern firm is bound together very differently, by the cultural effects of managerial persuasion.

The history of how Dutch entrepreneurs were able to leverage the in-place legal, political, and social norms that legitimated a guild-based (and constrained) citizenship into a modern form of corporate citizenship – and so create today's more purely economic entity – has yet to be fully worked out. Note the oft mentioned *Vereenigde Oostindische Compagnie* – founded in 1602 – is not a good example, given it evolved rapidly into a military and governing agency for the new Dutch Republic's colonizing. Joining it required an oath of allegiance. The focus here is on the multiple small firms (which we now call 'small and medium enterprises') the burghers founded that drove the Dutch Republic's emerging economy (de Vries and van der Woude, 1997). The historical break between the guilds and the modern firm is neither technological nor financial, for these means and instruments were already widely available; its essence lies in its commitment to a novel mode of administrative power. Part of the history of guilds is their eventual erosion as states became more powerful, for states had interests in economic growth the guilds did not. States waged war and were the populace's ultimate custodians, especially of the poor, indigent, or criminal. States needed – and still need – cash more than the guilds did, for the guilds' sights were on membership and honor rather than on international financial and political power. So perhaps the story here, as Smith suggested, is that these new firms' emerging economic power and greater economic efficiency helped them force themselves into the nation's political economics and displace guilds as inferior wealth creators.

While many wax nostalgic and argue today's firms should provide a richer cultural locus in which 'trust' and 'ethics' abound, as if they ever did in a bygone Golden Age, the modern firm is closer to being an apparatus for maximizing shareholder value that regards every factor of production and every participant as tradable, replaceable, and membership of passing consequence. The modern firm abjures the human and social obligations that marked the guild. It has become increasingly personified at law, albeit unnaturally, and seized on reputation and brand as significant self-images; employees are correspondingly depersonified, useful only for the services they provide, no longer recognized as long-term obligations. The guild participants' concern with reputation and honor was displaced by prioritizing shareholders' and managers' economic interests, all part of the rise of rational man, the self-maximizing isolate the Enlightenment ushered into the modern world, the antithesis of a 'state of honor.' Likewise the evolution of statistics (numbers in the service of the state) has transformed our citizenship, powered by improved record keeping and surveillance. The concomitant changes in our political democracy, especially in neoliberal thought, clearly buttress individualism at the expense of community. Khurana observed a similar dynamic in the US as the notion of managerial professionalism shifted from social duty to managerial and shareholder capitalism (Khurana, 2007; Spender, 2007). In short, the modern firm coevolved along with the turn to rationalist ideology and the modern surveillance state; they are made for each other. The history of managing is not a Whiggish journey toward economic perfection; rather it is the contingent result of today's norms of corporate citizenship as they engage today's growth-intensive socioeconomics.

Concluding Comments

Managing is only relevant to entities (firms) that are not self-managing – as self-organizing systems and efficient markets are thought to be. Managing can only be understood through the lens of a concept or theory of firms integrating the factors of production available in real markets into outputs that can be sold into real markets. The inputs and outputs are heterogeneous and of wide variety; land, labor, and capital, perhaps, or technology, finance, and employees' judgment contributions. Each factor implies a history of managing as integrative. The trickiest aspect is managing people into uncertainty-resolving judgments that generate appropriable economic value. Managing means getting specific individuals to engage specific uncertainties as they contribute their labor and judgment in ways that cannot be fully rewarded. Firms are therefore singular and indexical, and only exist and survive because they are, in part, an apparatus of social and economic exploitation as well as of economic value-creation. They are profoundly political entities so managing is a discrete political activity embedded within open zones in democratic capitalism. The history of the modern firm and the forms of management that create and sustain it can be explored through the notion of corporate citizenship and how that differs from other and previous forms of citizenship.

The complexities of managing can never be fully clarified because they arise at the collision of uncertainty and the firm's complex of social, normative, legal, technological, and other constraints (Spender, 2014). But today's corporate citizenship can be illuminated by contrasting it with that offered by the guilds, so treating guilds as historically transitional socioeconomic institutions that provided some of the modern firm's foundational principles and character. Overall then, the evolution of the modern firm is part of an interlocking history of ideological, political, legal, and technological change that led to (1) the 'invention' of the firm as a legal but unnatural person with political, legal, and social rights that differed from citizen's; (2) the legitimation of the subordination of individual rights to the firm's managers; and (3) the state as an increasingly rational-legal entity to which all citizens, individuals, or corporates, ultimately owe allegiance.

Abstract

This article attempts to clear away the confusion that has surrounded the notion of modernity. The primacy of the aesthetic dimension is recognized when considering the characteristics and attractiveness of modernity. The display of the historical process usually linked to the notion of modernity is followed by a specificity analysis of this polysemous and complex concept, attracting numerous contradictions and ambivalent views about the writings of Charles Baudelaire, Walter Benjamin, and Robert Musil. The relationship between sociology and modernity also is explored, with particular reference to the work of Georg Simmel.

If it is true that a notion is intuitive knowledge (*see* Knowledge, Sociology of), synthetic and inaccurate enough about one thing, then modernity belongs to this type of mental representation that, as opposed to concept, does not offer clearly defined contours of the abstract object to which it refers. We commonly agree on what must be understood by 'modern': that which appears, exists, or belongs to the current era or to a recent period, whereas 'modernism' expresses a preference against all traditionalism (*see* Sociological Traditions). Economists, sociologists, and development experts also know what 'modernization' (*see* Modernization, Sociological Theories of) means when expressed in terms of politics and equipment plans. They agree with Jean Fourastié that, in the 1920s, to modernize a factory meant to install machines there and to submit the workers to their rhythms, whereas now "it is to introduce into it a new working method, based, above all, on the means and faculties of men" (1969: p. 354). All those who deal with religious sciences (*see* Religion, Sociology of) know about the crisis of 'modernism', which condenses the doctrines and movements advocating renewal and adaptation of Catholic theology (*see* Catholicism) in relation to modern scientific discoveries and the general evolution of the world at the end of the nineteenth century and at the beginning of the twentieth century. Finally, nobody can ignore that modern style, 1900 style, and 'noodle' style are composed of floral ornaments – intertwining iris, Virginia creeper, and plane tree or chestnut tree leaves.

Numerous semantic samples, which relate to the modern or to what it specifies, could be attached to modernity. In particular, we should mention those that include ideas of custom, of *avant-garde*, and of doubt, as well as the refusal of traditional values (*see* Values, Sociology of). The complexity – paradoxically, as it would itself become the challenge – of modernity lies in the multiplicity of levels in which it is unfurled and in the uncertainty of the temporal framework that we tend to attribute to it. It appears to show solidarity toward 'progress' made in the field of science and technology; when applied to arts and culture, it can be conceived as being free from established rules, released from former achievements, and of new creation, original, unpublished. It is possible that modernity saw the light of day in the sixteenth century: Did not a French historian entitle one of his works *La Modernité du XVIe siècle* (*The Modernity of the Sixteenth Century*)? Leaving the modern period for the contemporary era, modernity emerges in the nineteenth century, when Chateaubriand created the term in a text dated 19 May 1833 and entitled *Mémoires d'Outre-tombe*, and in which he recounted that, on the outskirts of a town on the Danube,

> Vulgarity and modernity of customs and passports were contrasted with storm, the gothic door, the sound of a horn and the noise of a torrent.

It also is useful, from the beginning, to clear away the confusion that has surrounded the notion of modernity. We therefore recognize the primacy of the aesthetic (*see* Aesthetic Education) dimension that, at first sight, is nothing more than a rather vague constellation of ideas. Seen in this way, one might wonder how sociology should approach the subject, and which works should be consulted when we intend to examine its relationship with modernity.

The Characteristics of Modernity

Historically, modernity has a double origin: the Renaissance (*see* Renaissance) and the Reform (*see* Reformation and Confessionalization). From the beginning, it was the demonstration of a crisis, the symptom of a transformation – and in no way its 'analyzer.' It must be recognized that Jean Baudrillard ably demonstrated that modernity is not an analytical concept, but rather, by converting the crisis into a value, it is a form of regulation – and first and foremost, a way toward civilization (*see* Civilization, Concept and History of) – supporting a new mythology. It is not enough to say that the latter is centered on change; the ideological contents must be defined: These include categorical requirements that institute the 'tradition of novelty.' This argument owes nothing to Christopher Colombus, or to Galileo Galilei, and very little to Luther and Calvin. The idea of 'rupture,' to which modernity provides the rhetoric, however, is associated with the great discoveries, with the passage from geocentricism to heliocentricism, and to the theses of Wittenberg.

The development of this rhetoric continues through a series of processes: World rationalization, secularization (*see* Secularization) of thought, loss of one's fondness for community links (*see* Community, Social Context of: The US Case), and

assertion of individualism (*see* Individualism versus Collectivism: Philosophical Aspects). In France, we are aware of the strong moments of this movement. First, we have the quarrel of the ancient and the modern, in which the champions were, on the one hand, Boileau, Racine, Bossuet, La Bruyère, and, on the other, Quinault, Saint-Évremond, and Fontenelle. The last of these was the author of *Digression sur les Anciens et les Modernes*, which appeared during the same year (1688) that Perrault began his compilation of *Parallèles des Anciens et des Modernes* (1688–92). Descartes had already affirmed that there is no reason

> …to bow down before the Ancient because of their great age, it is more ourselves who should be called Ancient. The world is now older than before and we have a greater experience of things.

We see that the old image of dwarves perched on the shoulders of giants has reappeared. In fact, it was not only a question of specific literary value within the works of antiquity. The opposition was especially interested in the effectiveness of progress of intelligence and morality: The ancient remained attached to the idea of an original and 'natural' simplicity, whereas the modern believed in the beneficial effects of civilization (*see* Civilization, Concept and History of).

Another important step was the period known as the *Aufklärung*, the Enlightenment (*see* Enlightenment), the *Siècle des Lumières*, which in France was the setting for the adventure of the encyclopedia (*see* Encyclopedias, Handbooks, and Dictionaries). In a world plunging into obscurity because of the effacing of religious signals, there emerged a willingness to maintain an illuminated center – and to assume the heritage – far from the models that merely had to be imitated. 'Modernity' provided support for ideas of progress and freedom: *Laisser faire (les hommes), laisser passer (les marchandises)*: Let them do (men), let them pass (marchandises This injunction coined by Vincent de Gournay (1712–59), became the motto of economical liberalism (*see* Liberalism: Historical Aspects), an expression of modernity. Free examination, free expansion, free pleasure in fact cumulated their impact at the time of the Enlightenment, but it was not until the next century, with the continuation of the Democratic and Industrial Revolutions, that modernity acquired its full political and economic significance.

Without a doubt, modernity is the inseparable companion of industrialization (*see* Industrialization), of urbanization (*see* Urbanization; Development and Urbanization), and of the introduction of regular salaries, which characterize a productive society wholly placed under the sign of the division of work. It also is an integral part of a progressive movement toward a mass consumer society based on standardization. The new way of life that it engenders – of which dissociation of work place and living environment, as observed by Max Weber (*see* Weber, Max (1864–1920)), is just one aspect – corresponds to the organization of the 'modern' state, the centralized, the bureaucratic state (*see* Bureaucratization and Bureaucracy, History of), and the promotion of the individual as an abstraction, which in turn creates the combination, in the universal derealization exposed by Marx (*see* Marx, Karl (1818–83)), of the rationality of the state – henceforth, equipped with a constitution – and of private interests, which are linked solidly to ownership. The concepts we have just discussed are not, objectively speaking, the most essential part of what we are seeking to understand. This can be found in the anxiety that overtakes the individual freed from the old magic-religious mechanism and that will, in the end, only be alienated by new networks of mediation. Mobility has reached a state of subjectivity and has rendered the identity of the subject uncertain, so that from then onward, it will be predisposed to instability.

The Attractiveness of Modernity

If we see modernity man installed in a time-specific, historical era, that is to say in a new temporality that apparently excludes eternity, we again are making him the vector or the product of an ideology of rupture. Within a cultural context where everything seems to be contemporary, current, and immediate, contradictions follow on from each other and opposites unite – for example, standardization and the search for singularity, social integration and irruption of subjectivity, submission (to norms) and subversion (of forms), and so on. With the emergence of *avant-garde* (*see* Avant-Garde Art and Artists) – that is, the aggressive emancipation of models, which had been considered legitimate until then – the destruction of traditional frames and perfect examples, we are nevertheless passing from a period of modernity viewed as a rhetoric of rupture to an attractiveness for change.

In an incisive study, *Prosa der Moderne*, Peter Bürger (1988) perfectly demonstrated that

> …if it is true that philosophical thought is blocked because it is incapable of considering the catastrophe by which it is obsessed, it is time to discover the other medium which allows one to see clearly within ourselves, in other words the prose of modernity.

Thinking laterally, he also gave prominence to how literary knowledge and sociological analysis can cross paths. Among the authors of literary modernity whose writings have the power to take their own presuppositions as a theme, we must place Charles Baudelaire. We will not, however, refer to P. Bürger's (1988) subtle comments about the allegory of the poet of *Fleurs du mal*, we simply will recall how the critic, in *Curiosités esthétiques*, identified modernity by assigning, for the first time, the meaning that remains attached to it today.

In 1863, *Le Figaro* consecrated its famous chronicle to modernity, as seen through the street scenes drawn by Constantin Guys, 'the painter of modern life'. The quality that should exist in the heart of all creation is identified: it is 'movement'. 'And thus he goes, he runs, he seeks' and what is this 'modern' artist looking for? The goal he is aiming for being

> …other than the fugitive pleasure of circumstance (…), it is, for him, to release from customs what they can contain as poetical in the historical, to extract the eternal from the transitory.

Modernity "is the transitory, the fugitive, the contingent, the half of art whose other half is eternal and unchanging."

Baudelaire (1869) It is the resolution of a conflict, the reduction of tension between the ever-suspect outpouring of emotion and the unjustifiable steadiness of eternal beauty, the reconciliation – thanks to poetical works – of the requirement for emotional authenticity (via the insertion of work in the evanescence of daily life) and of a desire for eternity (which is satisfied by the freeing of the invariable from the contingent).

We clearly can detect the reasons for Baudelaire's strong delight in painting and music, and especially for the canvasses of clashing contrasts by Delacroix and the swelling music of the Wagnerian universe. There is an energy that gives dynamism to these works; it jostles and disrupts the emotional state of the person who contemplates or listens to them. Combining passion and control, Delacroix remains detached from all imitation of nature: He is the 'suggestive' painter and "what he translates is the invisible, the impalpable, the dream, the nerves and the soul." On this subject, Baudelaire observes that Breughel, with his dreamlike chaos, and Goya, the painter of the monstrous probable, figure among the initiators of modernity. Modernity is therefore neither topicality, nor contemporaneousness; one is less fond of it at a given time. It becomes an orientation toward a future-past and a discernment in the era of the 'provisionally eternal'.

At the same time, we are experiencing the assumption of imaginary. Toward this – which dilates as the symbolic becomes tense – there opens a space on canvass and score. A constructive imagination, the first constituent, governs its display that does not end with the imagination–deceptions generated by fancy. With passing movements of decomposition and recomposition, the form of the beautiful symbol of modernity is sketched, made up of strange things and devices that render the beautiful the antonym of the real. The caricature of Daumier, the hair-splitting of the universal exhibitions, and the calculated affectation of the dandy are equally make-ups, but not masking, of the real. During the Salon of 1859, Baudelaire gave meaning to the lie that is modernity, when he wrote that, after expressing his enchantment for the theater decor that concerned his artistic dreams

> …these things, because they are false, are infinitely nearer to the truth, whereas most of our landscape painters are liars precisely because they forgot to lie.

We also can identify the reasons that led Walter Benjamin to see the passive stroller in the intoxicating crowd as the 'hero of modernity', in his studies dedicated to Charles Baudelaire, *Ein Lyriker im Zeitalter des Hochkapitalismus* (1938–39). This is surely the poet of modern society who, in the agitated throng of large towns, feels the loss of experience intensely: for which the instantaneous real-life experience of innumerable shocks was substituted, became permanent, and could not be assimilated. In this situation, which is characterized by a new relationship to time – about which modernity no longer recognizes the accomplishment, having lost all sense of recollection and festive moments – he can respond by miming death. He can also, like Baudelaire, search within the 'correspondences' for an experience that will be pursued and protected from, and far from, the modern clash. In a general way, the loss of the 'aura' will be converted into a poetical experience.

An earlier text by Walter Benjamin, *Das Kunstwerk im Zeitalter seiner technischen Reproduzierbarkeit* (1935), provided a definition for this tendency of modernity to be in constant opposition to uniqueness and distance. The masses' appropriate images multiplied by technique; a new, democratic, community is formed, in which the concepts of creation, genius, and style fall into disuse as we move from the value of worship to the value of expression. Growing reproducibility leads to the decline in ideas of authenticity and uniqueness, of the authority of the original, all condensed into the 'aura,' which becomes a theological survival. In this perspective, modern art trivially signifies that by as many people as possible having access to its products. With the texts united within the title *Das Passagen-Werk* (1927–40), Benjamin aimed for a deeper comprehension of modernity in light of historical and dialectical materialism (*see* Analytical Marxism). Taking as examples, arcades, universal exhibitions, and Baron Haussman's destruction and constructions, along with photography and the bourgeois interior, he made the ambiguous demonstration of the process triggered by the fetish for merchandise. The creation of Parisian arcades, covered passages lined with shops and boutiques with their window displays full of goods, is identified as the moment when merchandise and technique seem to be liberated from art to appear free of all artifice, but once again they are surrounded by borrowed elements. Art becomes technique and, from then on, is placed mainly at the service of the market. It is draped with dreams of the past and transfigures the defaults of the present into works that reveal the utopia of the future. Another art that became fashionable during the nineteenth century was phantasmagorical art, which consists of showing phantoms through optical illusions in a dark room, leading to the assimilation of modernity with a phantasmagorical universe in which signs free of all substance proliferate and where, at the same time, the primacy of form is asserted.

Criticism of Modernity

The aesthetic dimension of modernity and the society in which it is inscribed both have been examined by Georg Simmel (1989–90) (*see* Simmel, Georg (1858–1918)). In his opinion, the world of modernity was in opposition to that of classical culture (*see* Classical Legacies), which was considered to be orderly and containing hierarchical values. In this world, where custom was represented as the summit of the change to which it was perpetually dedicated, was born a new living place – the large town inhabited by masses of people – and a new style of behavior appears that was characterized by the modern individual. Individualism (*see* Individualism versus Collectivism: Philosophical Aspects), its dominant trait, was no longer seen as a universal archetype, as it was in the ancient Latin and Christian world. The individual was conceived from now on as a totality, which German romanticism had glorified. Similarly, tragedy was no longer, as in ancient times, seen as a confrontation with an external destiny, but interiorized, so that the individual was not only man but also victim and torturer.

In this configuration, which stems from the movements and the disorder that it designates, 'modernity' appears as a sum of transformations and contradictions that Simmel attempted to

disentangle. People could be placed under the sign of conflict, thus providing one of the most important chapters of *Soziologie* in 1908, and in particular were well portrayed in art and religion. To persist, it is required to become consciously but implacably subjectivewithin itself: This is considered as the stylization of life expressed through its liberation. Rodin was selected to be the representative of modern art and interpreter of modernity, insofar as his sculpture was the representation of movement – as an expression of the soul – in relation to a renewed conception of temporality. In the same way that time is an addition of separated instants, movement is composed of a succession of instantaneous postures. This idea leads to condemnation of mechanism and of naturalism (*see* Naturalism), to the assertion that art, because it does not have to bear the 'train of reality', does not have to copy reality. Art (*see* Art History) is an original conception of the aesthetically modern, which is no longer that of the object, but of the subject, with its moods that are expressed in a portrait or a landscape.

All the Simmelian digressions on copy and creation, on distance and proximity, and on the tragedy of culture and the intuition of life, are harmonized into a single philosophy of modernity, which cannot be separated from general sociology. Lilyane Deroche-Gurcel (1997) perfectly demonstrated their complementarity, beginning with an explanation of how aesthetic points of view and sociological analyzes come together for Simmel. Two dissatisfying conceptions of modernity in art are revealed by the author of *Rembrandt – Ein Kunstphilosophischer Versuch* (1916). One provides him with a matrix as its only formal principle: The beautiful works are the girls and their shape. The other makes it the immediate expression of life: The original creations are born from strict contact with reality. Going beyond the hieraticism of art for art and the outburst of exuberant expressionism, Simmel saw in the interaction of life and form – an interaction that had been accomplished by both Rembrandt and Rodin – the outcome of modernity. It is this conception that led him to general criticisms or criticisms of detail: instant photography, which can give only a fixed expression of a reality, although it pretends to show movement; naturalism (*see* Naturalism), which is constantly at work in the *avant-garde*, closed in by the childish rejection of tradition and the boundless search for novelty; and, finally, all dogmatism.

Taking into account the main characteristic of modernity, that is the multiplication of the interactions among individuals, the dissolution of stable contents into transient elements, Simmel concentrated on studying, not constituted society, but socialization. The substitution of movement for substantiality is in correlation with that of the *Vergesellschaftung* in the study of the *Gesellschaft*. It is accompanied by the abandoning of the system for function, of the structure for process, and of the status for role, behavior, and attitude. It supports the election of the fragment compared with the totality and of the form compared with the contents. In this respect, the sociology of Simmel, more than any other, has a hold on modernity that signifies, apart from the secession with stability, the loss of all substantial contents. Here, we can observe the relationship that exists between modernity and melancholy.

What is significant, from this point of view, is the analysis of indifference: Simmel thought of it in terms of melancholy, by observing within certain aspects of socialization (customs, coquetry, adventure, or sociability; the politeness of a detachment without despair) the resurging of melancholic syndromes within the species of their form – depersonalization and a-historicity – understood by their sociological meaning. Finally, Simmel underscored the ambivalence of modernity. Although movement in fact appears to be carried off in a flow of tormented forms, it in fact offers itself to the serene contemplation of the amateur who sees in the work of art of modernity, not the deceptive immobilization of life but rather its stylization.

Generally observed from above, modernity could just as well be observed from below, as fragile historical periodizations. Dedicated to postmodernity, the works of Colin Campbell (1987), David Harvey (1989), Zygmunt Bauman (1989, 1992, 1997), and Barry Smart (1992) draw in a hollow a representation of modernity. A Fordist method of production, a division of the society into classes and mass consummation would be the last traits to have been presented by modernity – finally discredited in and by totalitarian barbarism.

In this perspective of historical framing, we equally discuss a 'late modernity' of 'high modernity' (A. Giddens) or a 'liquid modernity' (Z. Baumann). If for other authors who used the concept of 'postmodernity' (J. Baudrillard, J.-F. Lyotard, M. Maffesoli), the change of era, social, and cultural frame are implicit, A. Giddens and Z. Bauman highlighted the richness of the concept of modernity by pointing out a late phase of the evolution of this historical period. The approach of the Canadian sociologist Charles Taylor shows a similar view. The author examined in a critical manner the connection between modernity and secularization (*see* Secularization) and looked for a solution for the new challenge of the modern identity. At the same time, the individual demands respect for his 'dignity' (concept replacing historically the one of 'honor') and for his 'uniqueness'. The concept of multiculturalism, examined in a critical manner, nevertheless is considered by the author an unquestionable reality, assumed by most of the societies. It becomes thus necessary to synthesize the concepts of multiculturalism, multiple identities, universalism trend, and authenticity recognition.

We must equally underline that the syntagm of 'late modernity' evokes the subtle analysis of 'late antiquity', by Peter Brown, and his predilection for Gibbon's work, in which the author has the eye of a comparative historian rather than the one of a decadence thinker – 'sociologist of the imperial system', knowing how to reveal the institutional change and the beginning of a new social setting.

The profound analyzes made by P. Brown on the style, institutions, creativity, and concept of 'sacred' in the late antiquity (*see* Ancient Greece and Rome, History of) could serve to analyze a new shift of approach in the modernity.

We could equally highlight that the idea of decadence, which seems to suddenly appear as a rejection of certain aspects of the modernity, manifests particularly vividly at the end of nineteenth century. The concepts of antique decadence and contemporary decadence entangle particularly in the work of J.-K. Huysmans (*A rebours*, 1884, *Là-bas*, 1891).

The postmodern era therefore would begin with the jamming of the effects generated by the rationalization of the world and would be followed by the coming of social

configurations that from then on would be commanded by new information and communication techniques (*see* Information Society). The deconstruction of what modernity edified therefore would be put into operation. In the field of urbanism and architecture, the cities of Brasilia and Chandigar show well what modernity meant during the twentieth century: a utopia of simplicity that does not recognize the complexity of life.

Retrospectively conceived in this way, modernity found itself deprived of many of its characteristics, which were transferred to the age that closed it down: the mix of the present with the past, of the new with the archaic, of cultural relics with technical gadgets. Subject to trial by a plurality of readings and interpretations and according to segments of severed time, modernity can less be a rupture than a response to this – by amalgamation. Above all, the postmodern point of view concerning modernity, whose horror is exposed, leaves behind the tragic that profoundly touched it. It is therefore a reducer, the better to reveal the return of complexity, which led to its adoption.

In fact, modernity man is seized by this complexity. It is Ulrich, alias Musil (1931) of *Der Mann ohne Eigenschaften*, the man 'without quality,' who was devoted to the juxtaposition of partial histories. Before the series of events crossed by the crisis of sense and before the difference between physical reality and psychic reality, which increasingly is being demonstrated, the question is this: How does one summarize it? How can we find the balance between the vital, the emotional, the affective and the control, the criticism, and the censure? Within the Kakania, Austria–Hungary mythical, modernity is an impossible synthesis. But it is also the uneasiness to which we are condemned as soon as, in the order of politics, a work interrupted by reduction of admiration or respect renders the calls for trust and esteem hardly audible and credible.

We should distinguish two registers within the study of modernity. The one that we will qualify as 'ideological' is the most frequented by sociologists. In the ideology of modernity, some see a conservatism via change, others see a spectacular ambiguity, and yet others see a culture of daily life. On another level, which, for want of a better term, we will call 'existential,' we must situate all that was produced with the weakening of subjectivity, with the assertion of individualists, with the perversity of human relationships, which are just as much aspects of modernity. It is at this level of analysis that we must position ourselves to examine the psychosociological consequences of self-constitution, according to which modernity was unveiled and which always will be, although in changing forms, the return of the same.

Abstract

Anthropology is a modern study of human existence in which the anthropos becomes an object of knowledge and also a technique of modern power. The field readily acknowledges that it is both a product, and an interrogator, of modernity. This relationship has given anthropology its existential doubling, as an extension, and as an undoing, of the taken for granted aspects of Western modernity. For much of the twentieth century, anthropologists have used ethnographic findings to question the assumed aspects of the historical framing of modernity and its others. Another feature of anthropology's approach to modernity is through the notion of plural modernisms, which seeks to capture the particularistic experiences of others in encounters with modern Western forms. The most promising approach has been to treat modernity as a specific ethnographic project, one that tracks the spread of political and social rationalities, and their production of new techniques, social forms, and subjects in a variety of ethnographic settings. Anthropology as a field and an ethnographer's craft is especially well suited to identify the ever shifting webs of rationalities that constitute our plural worlds, and to pose the question of modernity itself as a paradox about humanity.

Modernity as Frame and Problem in Anthropology

The idea of modernity has operated as a historical framing for anthropology, but the categories of what is modern (radically new) in the human condition have shifted throughout the history of the discipline. At a simple level, we can say that the social sciences are generally about the study of modern societies, so why would anthropologists discuss modernity as an isolated area? We can say that anthropology is a *modern* study of human existence in which the *anthropos* becomes an object of knowledge and also a technique of modern power. For a discipline that produces its knowledge through an intimate experience of the (exotic) other, the field is particularly unique in that it is both a product, and an interrogator, of modernity.

This relationship of anthropology toward modernity has given anthropology its existential doubling,as an extension, and as an undoing, of the taken for granted aspects of Western modernity. For much of the twentieth century, anthropologists worked within the historical framing of modernity and its others, and used ethnographic findings to question the assumed aspects of Euro-American modernity and progress. The second distinctive aspect of anthropology's relation to modernity is as plural modernisms, as a way to capture the particularistic experiences of nonmodern or subaltern others in encounters with modern Western forms. The most promising approach has been to treat modernity as a specific ethnographic project, one that tracks the spread of political and social rationalities, and their production of new techniques, social forms, and subjects in a variety of ethnographic settings. Anthropology as a field and an ethnographer's craft is perhaps well suited to identify the ever shifting webs of rationalities that shape our plural worlds, and to pose the question of modernity itself as a paradox about humanity.

Modernity and Its Others

From its very beginning as an academic discipline, anthropology has dealt with modernity as historical encounters between the modern and the nonmodern, and the social consequences that followed from such transformations. Initially driven by an evolutionary logic, social anthropology was dominated by an opposition between the so-called primitive societies characterized by 'premodern' customs regarding magic, sexuality, and exchange which acted as a foil for modern ideas such as rationality, the Oedipus complex, the nuclear family, and the profit motive. There was also a more radical epistemological project to discover a cultural logic embedded within the native social system, giving it a positive valence that established a rationality alternative to that of European cultures. Anthropology thus studied those aspects of other cultures that stripped away the taken for granted nature of Euro-American modernity, and introduced a reflexive element into the 'science' of human knowledges. This implicit critique of the rational and scientific assumptions of European modernity gradually included the indictment of racism, as research conducted in the shadow of European imperialism exposed its destruction of native cultures and its dependence on racism in colonial systems. Claude Lévi-Strauss ruminated on Europe's destruction of the premodern as inseparable from the loss of its own cultural ideals.

In the United States, the pioneers in anthropology participated in debates over the fate of traditional cultures under modern conditions. Nineteenth-century 'salvage anthropology' engaged in a valiant attempt to record dying cultures, sometimes rendered in utopian terms. By the early twentieth century, Franz Boas established *cultural* anthropology as a field that spoke out against the human costs of Western conquest, colonialism, and racism. Boas sought to develop a scientific language of cultural differences and universal human dignity as inescapable aspects of modern humanity. During World War II, Margaret Mead and Ruth Benedict popularized the study of national identities, often contrasting the rationality of American society with premodern others.

In the post–Second World War era, classic social theory in the writings of Marx, Durkheim, Simmel, and Weber

replaced earlier evolutionary perspectives on cultural change. Capitalism is now taken as the utterly revolutionary force that has created the modern world by radically breaking with the past. Market civilization tore asunder personal relations, destroyed communal social systems, and introduced egotistical calculations and the modern state to premodern worlds. Thus emerged a strong anthropological tradition to study the varied impact of the capitalist juggernaut on native social forms, subjectivity, and social change.

Commodity Production and Fetishism

Most scholars would agree that modernity began with the original capitalist transformations in the North Atlantic world, and their effects on the direction and limits of social change for all of humanity. For Marxist anthropologists, the most resonant story was the ways peoples of the new and ancient worlds were displaced and compelled to engage in commodity production. The works of Eric Wolf (1982) and Sidney Mintz (1985) show that exploitative market relations transformed colonized peoples into new kinds of alienated human beings, as commodity relations dissolved preexisting cultural relations among people, uprooting them from former ways of life.

A significant contribution of anthropology is to show that the market system, contrary to Marx and Karl Polanyi, did not gradually replace all other social forms, but rather interacted with other social systems in the differentiation of modern society. The 'modes of production' school demonstrated that kinship- and community-based systems in Africa, Latin America, and the Asia-Pacific became functionally articulated with the capitalist system (Godelier, 1977). Ethnographies captured in vivid and concrete detail the parasitic dependence of capitalism on the labor of slaves, sharecroppers, cash-cropping peasants, and women in the developing world. Premodern labor forms and the domestication of women in far away places have historically been part of capitalism, and therefore a part of modernity itself. Forms of servitude such as guest workers and maids, often organized along gender, ethnic, and national lines, are an integral part of advanced capitalist societies. These cultural others furnish the images of the premodern other to contemporary capitalism's own self-reflection.

The concept of commodity fetishism influenced ethnographic studies of how the market, bureaucracy, and mechanical media erode and reform indigenous notions of sociality and personhood. For over a century, anthropologists have decried the destruction or debasement of native cultures that came with capitalism, Christianity, and foreign rule. Anthropologists have documented the social despair, millennial movements, and rituals of violence inspired by missionaries, travelers, and traders. Another perspective mines the folklore and magical beliefs of colonized peoples for their hidden critique of the objectifying meanings of capitalism. The fetishization of market goods creates conditions for social competition, and gives rise to new hierarchies along lines of town and country, class and gender differences. Across the world, the mass production of culture, including soap operas and beauty contests, engender a variety of cultural configurations, displacing revolutionary sentiments with new desires and confusion.

Modernity and the Spread of Rationality

The Weberian view in anthropology dealt with the universal diffusion of the peculiar social rationalities of Western capitalism to traditional societies. Like much of the social sciences in the 1960s and 1970s, Weberian-inflected anthropology was framed by a modernization theory which ranked societies according to the degree of their adoption of modern Western values and institutions. In a series of studies on Indonesia, Clifford Geertz (1963) observed that the limited adoption of rational values and entrepreneurial forms such as capital accounting 'stranded' a country seemingly poised to take off into industrial capitalism. Geertz observed that Javanese cultural and economic spheres were firmly integrated by an overriding communal ethos that thwarted the rise of individualism and impersonal relations required by market organization. The Weberian assumption that economic rationalization would be gradually split off from other spheres was itself challenged by studies of advanced capitalist societies. Marshall Sahlins (1976) argued that in American society, practical reason can be shown to be informed by religious and aesthetic schemes of meaning. But clearly, the project to decenter certain dominant Western conceptions of humanity must be embedded in an analysis of how these schemes of meaning are transformed in relation to the power dynamics of class, gender, and race.

The New Modernisms

By the early 1980s, the end of the Cold War spelled the decline of universalizing theories of modernization, and new generations of anthropologists rejected the totalizing, evolutionary assumptions about social change. The writings of Michael Foucault, and the rediscovery of Nietzsche, popularized understanding about the intimate relations between knowledge and power and focused intellectual projects not on things but on the conditions of emergence of new forms that have been built into the conduct of life. Foucault's *The Order of Things* (1970) first sets out the ways knowledge/power schemes shape and normalize objects of knowledge, and his later works have had a powerful effect on anthropology's analytical techniques and self-perception.

But the so-called postmodern challenge, and an influential text, *Anthropology as Cultural Critique* (Marcus and Fischer, 1986), became symptomatic of the misrepresentation of the crisis of knowledge as simply a 'crisis of representation.' The self-reflexive turn caused many to scale down their anthropological project to an experiment in writing ethnography. First, a 'politics and poetics' of representation approach seeks to redress the temporal and political inequalities between ethnographic informants and the anthropologist (Clifford and Marcus, 1986). Second, feminists – concerned about partial truths and informant empowerment – popularized multivocality to undercut the authority of the author. Third, a radical deconstructionist approach privileges language and writing over the theorizing of social forms. Such ethnographies seek to capture the jarring experiences of colonial and proletarian subjects, both to

uncover the hidden 'truths' of subaltern suffering and resistance, and to subvert objectifying categories of description. Fourth, the so-called 'culture/power/history' orientation takes modernity as a historical cultural formation, embedding the study of discourses and cultural politics within the specific political economic contexts. These varied approaches seek to capture the particular conjunctures and disjunctures of discourse, culture, and power in encounters with Western power and knowledge. But unlike experimental ethnographies of earlier generations, the current postmodernist assault on the ideological constitution of Western social science does not offer an alternate method for studying schemes of practice, their logics and limits, and possibilities for transformation. Thus, postmodern approaches represent a detour in the anthropological theory of modernity. They do not develop a positive concept of modernity or analytical categories that can be applied to the systematic study of social forms that will allow for theoretical generalization.

Modernity as Political and Social Rationalities

The anthropological focus on modernity as an ethnographic problem in its own right was stimulated by recent European social thought. In American anthropology, with the help of his American interlocutors Herbert L. Dreyfus and Paul Rabinow, Michel Foucault's *oeuvre* came to have a wide-ranging influence on different approaches to questions of modernity. The fundamental question was not to treat modernity as an analytical opposition to given ethnographic realities, but rather to take modernity itself as an ethnographic object, as specific social and political rationalities configuring particular worlds.

Foucault's *Discipline and Punish* (1977) has been especially influential in the anthropological analysis of modern power. We can identify three conceptual clusters: (1) a positive (not repressive) 'capillary' notion of modern power as circulating practices arising from multiple domains; (2) the role of knowledge/power schemes in proliferating social norms and forms that produce subjects; and (3) the specific technologies of governmentality – grids of knowledge/power, mechanisms of surveillance – that govern our everyday behavior and make us particular kinds of modern human beings. Such a reconceptualization of modernity as projects and schemes of power is particularly suited to the ethnographic method of tracking the logics of everyday attitudes, habits, and practices (Bourdieu, 1977). It becomes apparent that the goal is not to arrive at some grand theory about modernity, but rather to scrutinize the concrete manifestations of emerging social practices, norms, and cultural politics in relation to the market, the nation state, and to globalizing forces.

Alternative Modernities

The Foucault effect on thinking about colonialism and postcolonialism shifts attention from reactionary cultural formations to strategic modern projects. More attention is now given to social rationalities – law, hygiene, sex, and labor disciplines – involved in civilizing colonized societies and subjects. The study of postcolonial development itself is reconceptualized as regimes of discursive power that have material effects on shaping the politics for remaking the Third World (Escobar, 1995). The anthropology of imaginary modernities – narratives that depend on the creation of the otherness of their own pasts as well as of the West – show that in the new China, different generations have been shaped by visions of a movement from a dark past into a bright socialist future. Indeed, for other countries, folk theories of modernity may even incorporate backwardness, thus subverting metropolitan development programs.

The concept of 'alternative modernities' risks reifying native views of modernity, and it will have more purchase if ethnographic attention is also paid to the specific social practices and forms that are distinctively modern. For instance, anthropologists note that the obsessive promotion of marginal cultural practices may engender a 'spectacular modernity' in societies greatly transformed by industrial capitalism and deeply anxious about the loss of national identity.

More grounded approaches have explored the disciplining effects of agricultural programs and bureaucracy in shaping developing societies (Ferguson, 1990). Others consider how modernity becomes a state project in developing and postsocialist countries, focusing on the interactions between the market and other social systems that discipline civil society. Such ethnographies demonstrate how the novel forms of governmentality and governance, evolving in relation to globalizing forces, are dialectically linked to selfdescriptions of alternative configurations of modernity.

Modern Schemes and Subjectivity

In *French Modern* (1989) Paul Rabinow opens up the space between the high cultures of modernity and the experiences of ordinary life as a domain of 'middling modernity' where social technologies encounter and regulate everyday sensibility. By seeking the coming into being of modernity in the mundane details of daily life, ethnographers present a complex picture of how the nondramatic norms and forms are constitutive of what it means to be human in particular societies. Perhaps anthropologists have gone further than other social scientists not only in grounding modernity as a particular set of rationalizing norms and practices, but also to specify the locations of different kinds of rationality in modern, universalizing institutions. Ethnographic scrutiny delineates how different regimes of power/knowledge have identified, processed, and constituted particular kinds of modern subjects in runaway factories, hospitals, and scientific laboratories and in utopian cities. Thus, modernity as an object of anthropological inquiry itself is a shifting target, as anthropologists track specific technologies in a range of ethnographic situations, and allow for comparison beyond cultural particularities.

Cities and the Reconfiguring of Citizenship

The metropolis, as Benjamin and Simmel have noted, is the *locus classicus* of modern sociality, the setting for the most extreme expressions of individual freedom and impersonal objectification. Earlier anthropological studies of urban life focused on the retention of village bonds among migrants or the maintenance of ego-centered networks among working

class communities, as a defense against the alienating effects of modernity's flux. Indeed, more and more, cities rather than nations have become the salient sites for examining the gap between political citizenship and the experiences of different categories of persons who have been excluded or subordinated within the ideal national community. A central problem in conceptualizing modernity then is an ethnographic investigation of the mechanisms and routines of governance and the practices of subjects being thus constituted as administrative subjects of particular cities, zones, and nation-states.

There has been a spate of ethnographies on immigrants, drug-addicts, prisoners, street-persons, youths, the working poor, and racial minorities protesting their illusory juridical status and exclusions from the 'liberal community.' Generations of anthropologists have studied black ghetto culture and poor urban neighborhoods, stressing the differential forms of integration into American society. More recent works explore how marginalized urban groups formulate their demands for substantive rights – to schooling, housing, clean water, cultural difference, and respect – from the state and fellow citizens in Western democracies (Holston, 1998). A concept of citizenship, not simply as imposed rights for abstract individuals, but as a set of contingent, negotiative relations between local authorities and self-making subjects, suggests a distinctly modern form of state-subject relations and subject-making.

Transnationalism, Differentiation, and Subject Formation

Of course, the modern condition now includes the proliferation of transnational networks that are transforming earlier understandings about community, mobility, and belonging. In our globalized world, modernity is increasingly understood and experienced in terms of transnational processes and webs of relationships shaped by the intensified flows of people, images, knowledge, and practices in everyday life. Such reconfigurations of social life and connections unsettle earlier anthropological notions of culture, community, and identity, suggesting that it may be possible to talk about a global ecumene spawned by intensified cross-border flows and exchanges (Hannerz, 1992). An approach to the cultural dimensions of globalization (Appadurai, 1996) suggests that the spatial and imagined coordinates of culture and community are now shaped by diasporic communities that are in the process of becoming 'postnational.' The category of the transnational imaginary, however, is an indeterminable unit of analysis, and the visions of global companies, multilateral agencies, and diasporic networks are all rather different. The voluntary flows of tourists, intellectuals, expatriates, and businessmen should be theoretically distinguished from the forced homelessness of migrant workers and refugees.

How are such imagined communities constituted in relation to the variety of social systems that have been produced and proliferated by globalization? Accelerated border flows have multiplied specific configurations of subsystems that go to make up particular worlds. While sociologists have focused on the materiality of the new technologies – time-space compression and time-space distanciation – anthropologists seek to sharpen questions about what new modern cultural forms and subjects are emerging in different places, and what alternative cultural logics may be at work (Ong, 2000). Transnational institutions and formations privilege new kinds of corporate subjects who internalize the norms of mobility, flexibility, and competitiveness (Martin, 1994). A further direction investigates the rationalities that go into the invention of new techniques, practices, objects, places, and subjects, configurations in which the meaning of 'the human' is problematized (Rabinow, 1998). Such projects will require us to go beneath the rhetoric of globalization and engage in multisited ethnography that can track the performative and migratory aspects of rationalities – in science, medicine, business, bureaucracy – that are shaping modern subjectivity in a variety of domains. Attention to new forms of governmentality enables us to ask what kinds of rules we have set up for ourselves to be considered modern human beings.

Living with Uncertainty

But the operation of rationalities is incomplete and contingent, and globalization has proliferated risks – volatile cash flows, unsettling information, diseases, toxic wastes, light arms, and bioscientific inno- vations – that expose everyone to the irrationalities of modernity. Capitalism has intensified the dominance of space and proliferated the social forms of modernity. Thus, in a world where the globalization of contingency is 'modern society's main attribute' (Luhmann, 1998), our thinking needs to go beyond simply the perception and containment of risk. What remains to be investigated is how risks enter into the calculations of everyday life not as an independent but as a dependent variable.

There are signs that the future directions of an anthropology of modernity will concern itself with how societies and individuals live with uncertainties and absorb risks in their everyday routines. What do modern people problematize in their everyday life, and how do they solve problems? In the intersecting realms of health, science, morality, and capitalism, for instance, anthropologists have explored the ways people cope with the AIDS pandemic, the threats of nuclear plants, and the politics and moral perils of human genomic research. The study of divergent human fate as well will attend to how heterogeneous social spaces – global cities, production zones, blighted borderlands, postsocialist formations, refugee camps, and cross-border networks – are experimenting with different ways for ordering human sociality.

While the anthropology of modernity has a shifting target – the particularistic configurations of contemporary social life – there is a fundamental unity in the ethnographic diagnosis of the particular techniques, norms, and practices that go into the constitution of modern human subjects in specific fields of power. The ethnographic method is ideal for identifying new devices, arrangements, and techniques, and for attending to the performative aspects of emerging practices within an actor-network formulation (Latour and Woolgar, 1986[1979]). Our methodology as well must absorb the uncertainties of our human science, and theory must be based in an ever-widening spiral of observations beyond the immediate field situation. The challenge is for anthropologists to wed an ethnographic analysis of the practicable, strategic

features we take to be characteristic of modern society with their interpretive, moral aspects.

For all the self-reflection and criticism, the project of anthropology remains one of a rigorous and systematic exposition of emerging worlds. Such a methodology – whether to study the interactions of functions systems, modes of ruling, modalities of subject-formation, biotechnological development, or the management of risks they all entail – allows for linking the particular with the general, the local with the global, the structural with the interpretive dimensions of modernity. By identifying the social and political rationalities constituting our plural worlds, we may ask whether we want to remain the kinds of human beings we have become. Modernity is both the condition and the decision about the future.

Abstract

Modernity is one of the central concepts of sociology. Typically, its emergence is located in the processes of economic and political revolution in Europe in the eighteenth century. Such an understanding conflates Europe with modernity and renders the process of becoming modern, at least in the first instance, one of endogenous European development. Coterminous with this argument is the idea that the rest of the world was external to these world-historical processes and that colonial connections and processes were insignificant to their development. This is challenged by more recent critical understandings of modernity associated with postcolonial and decolonial thought.

Introduction

'Modernity' has long been the dominant conceptual frame for social and political thought, sociology, and the social sciences more generally. The repercussions of the French Revolution and the processes of industrialization stimulated debates about the emergence of a *modern* world (modernity) and this world was held to require a distinctively *modern* form of explanation (sociology). The sociological understanding of modernity typically rests on ideas of the modern world associated with the processes of economic and political revolution located in Europe and underpinned by the earlier cultural changes brought about by the Renaissance, Reformation, and Scientific Revolution. Such understandings conflate Europe with modernity and render the process of becoming modern, at least in the first instance, one of endogenous European development. At the same time, the rest of the world is regarded as external to these world-historical processes and colonial connections are seemed to be insignificant to their development.

While accounts of the industrial and French revolutions – and, by implication, of modernity itself – have not remained unchanged over time, what has remained constant has been the historiographical frame – of autonomous endogenous origins and subsequent global diffusion – within which these events are located. As such, not only have 'others' not been recognized as constitutive of the canonical 'twin revolutions,' but also the potential contribution of other events (and the experiences of non-Western 'others') to the sociological paradigm of modernity has rarely been considered. This article will first present the standard, dominant genealogy of the conceptual history of modernity before addressing the alternate genealogy as coloniality–modernity. It will close with a discussion of the necessity of developing our concepts through an acknowledgment of broader, connected histories and sociologies.

Modernity and the Social Sciences

The dominant accounts of modernity within the social sciences rest on two fundamental assumptions: *rupture* and *difference* – a temporal rupture that distinguishes a traditional, agrarian past from the modern, industrial present; and a fundamental difference that distinguishes Europe from the rest of the world. These paradigmatic assumptions, Gurminder K. Bhambra (2007) argues, have framed both the standard methodological problems posed by social inquiry and the explanations posited in resolving them. They have also demarcated the disciplines themselves with sociology's remit being 'the modern,' while 'the traditional' has been that of anthropology, with 'sociological laws' common to both.

Whatever their other differences, the early sociologists believed themselves to be living through a (or perhaps *the*) great transformation in history and were concerned with understanding how it had begun and influencing how it would be brought to the completion they believed to be inherent within it. This was done through an engagement with ideas of historical stages. Once the general pattern of historical development was known, it was believed that the trajectory of development for other societies could be ascertained without direct research as all human societies were deemed to follow the same pattern; one which had been established by Europe. This built on the earlier tradition of the Scottish Enlightenment, which developed understandings of progress within human societies in relation to ideas of successive stages in historical development.

This was taken up and developed in the twentieth century by Talcott Parsons (1971), who argued that a common origin and shared heritage allowed for the evolution of a 'European system' of modern societies that could be understood in its entirety as differentiated from both earlier societies and from the rest of the world. Jürgen Habermas (1996), in turn, argued for modernity to be understood as an 'unfinished' project where the future was not about the reproduction of the present, but was considered to be a space for the further development of projects and trends. The 'unfinished project' is the bringing to fruition of what is already predicated in the Western experience.

Modernization Theory

Following in the classical tradition of sociology, modernization theory took as its idea of change the standard notion of a linear movement from a traditional past to a modernized future.

Explanations of the processes of modernization were primarily located in the context of a historical understanding of societies, where each form was deemed to be superseded by a progressively higher one. Traditional, or premodern, societies were put forward as objects of comparison with societies already deemed to be modern and the problem was set up in terms of accounting for the historical transition from one to the other. The debate on convergence around modern institutions and the economy, however, also occurred in the context of counterclaims arguing for *divergence* around issues of culture and political organization.

Parsons (1971) was particularly interested in understanding the implications of the transition to modernity and looking at why the breakthrough to modernization had not occurred elsewhere than in Europe. In common with most other theorists at the time, he believed that modern society had emerged in the West, and that this provided the base from which the *system* of modern societies then developed. Modernization scholars, such as S.N. Eisenstadt (1974), also believed that Western modernization should be used as a model of global applicability and other societies classified in terms of their relative modernization in comparison with this model; that is, other societies were to be studied in terms of the extent to which they approximated the characteristics of Western industrial societies. While becoming modern in the first instance might derive from peculiar circumstances which were historically contingent and even perhaps unlikely (for example, as set out by Weber in his study of the Protestant Ethic), once Europe had become modern, it was deemed to be able to show the way to the rest of the world as a model to be imitated. The birth of modernity, it was believed, could be induced.

Reinhard Bendix (1967) usefully summarizes modernization theory as resting on three related assumptions: first, an understanding of 'tradition' and 'modernity' as mutually exclusive; second, social change occurring as a consequence of phenomena internal to the society changing; and third, a belief that modernity would eventually replace tradition and, in doing so, would have the same effects across the globe. In this sense, modernization theory rests on a notion of *convergence* whereby the difference of other societies – as constituted through their traditions – would be erased through the process of the global diffusion of Western institutions. Once the structures of modernization extended to other areas, it was believed that the previous indigenous patterns, or structures, would change and that change would be in the direction of the relatively modernized societies.

While this position was largely dominant within the debates on modernization, it was not uncontested at the time, for example, by Dean Tipps (1973). Further, critical scholars, such as Henry Bernstein (1971), believed that using notions of a stagnant past, where the differences among societies were not regarded as relevant to the issue of modernization, and a dynamic heterogeneous present, both distorted the character of traditional societies and obscured understandings of the different forms of relationships between traditional societies and, what were regarded as, new institutions. This body of work came to be known as underdevelopment or dependency theory.

The demise of modernization theory, and related understandings of modernity, was associated with the explicit move away from structural–functional explanations in sociology. The latter was associated with the rise of more radical approaches, particularly those influenced by Marxism, and the related decline of Parsons. The fall of communism in the 1990s, however, reversed these sensibilities. For a number of commentators, the convergence thesis which had been discarded had turned out to be confirmed with Francis Fukuyama most famously proclaiming a new 'end of history.' This is the context in which some writers, most notably Eisenstadt (2000), returned to modernization theory seeking to challenge this triumphant liberalism, while also acknowledging the force of events. At the same time, the processes of decolonization, which had been the initial context for modernization theory, had themselves given rise to postcolonial critiques of the Eurocentrism of dominant understandings of modernity. The new paradigm of multiple modernities, then, was articulated in relation to these varying concerns.

Multiple Modernities

Decolonization in the 1960s was followed by the fall of communism in Europe in the late 1980s and 1990s. The perceived seismic shift in the global order – in particular, globalization being seen as the creation of a world market after the breakup of the Soviet-dominated economic bloc – renewed sociological debates about the nature of the modern world leading to the development of a new paradigm, that of multiple modernities. While for some, such as Fukuyama, these events confirmed the convergence claims of modernization theory and the role of the United States as 'lead society,' for theorists of multiple modernities, the removal of 'cold war' constraints instead allowed for greater divergence. The insistent claims of scholars from the Third World – be they theorists of underdevelopment or then postcolonial theorists – also required engagement and address.

Theorists of multiple modernities, such as Eistenstadt and others writing in Daedalus (2000), believe that, in outlining their new approach, two fallacies are to be avoided. The first, associated with earlier modernization theories, is that there is only one modernity. The second is that of Eurocentrism or, in their words, Orientalism. The argument is that while the idea of one modernity, especially one that has already been achieved in Europe, would be Eurocentric, theories of multiple modernities must, nonetheless, take Europe as the reference point in their examination of alternative modernities. Thus, while theorists of multiple modernities point to the problem of Eurocentrism, they do so at the same time as asserting the necessary priority to be given to the West in the construction of a comparative sociology of multiple modernities. As such, multiple modernities continue to be understood as derived from the creative appropriation, by those that followed, of the institutional frameworks of modernity that are seen to originate in Europe, and so the problem of Eurocentrism remains integral to the new paradigm.

Within the approach of multiple modernities, modernity is understood simultaneously in terms of its *institutional constellations* as well as a *cultural program*. Understanding modernity in this way allows scholars to situate 'European modernity' – seen in terms of the conflation of the institutional and the cultural

forms – as the originary modernity and, at the same time, allows for different cultural encodings that result in *multiple* modernities. For example, Nilufer Gole (2000) reflects on the idea of modernity from what she terms its Islamic edge, that is, Turkey, in order to discuss non-Western patterns of modernization. The idea of multiple modernities, then, is consistent with the idea of a common framework of modern institutions – for example, the market economy, the modern nation-state, and bureaucratic rationality – which originated in Europe and was subsequently exported to the rest of the world. This explains the apparent paradox that theorists of multiple modernities can dissociate themselves from Eurocentrism at the same time as apparently embracing its core assumptions. Further, in charting the development of specifically *multiple* modernities, scholars suggest that the first radical transformation occurred in the Americas, followed by the communist and national-socialist types in Europe. Not only modernity, then, but also multiple modernities are seen to have their origin in Europe or the Western civilizational framework at large.

Similar problems can be seen in the proliferation of theories of alternative modernities, global modernities, hybrid, and entangled modernities despite it seeming that the debates around these issues have moved beyond their initial, limited Eurocentric understandings of the world. In a collection of articles on alternative modernities, Dilip Gaonkar (2001) suggests that the emergence of the debate on alternative modernities reinforces the fact that something specifically modern is held to be inescapable. The West is understood as the major clearing house of modernity and in its globalization has traveled from the West to the rest of the world meaning that non-Western peoples must now begin to engage their traditions with modernity in different forms of hybrid 'modernities.' These assertions rest on a number of assumptions not least that there is an original modernity which was born in and of the West, and that the West is significantly different from the rest of the world such that while it can enjoy an original modernity, everybody else has to make do with a hybrid version, in which different modernities are no more than the combination of the adopted 'originary' form with 'nonmodern' elements. Gaonkar (2001) argues that a minimal requirement for thinking in terms of alternative modernities is to opt for a 'cultural,' as opposed to an 'acultural' theory of modernity which enables us to understand how non-Western cultures have tropicalized, or domesticated, key features of modernity. Even though the idea of modernity is seen less as the terminus toward which non-Western peoples constantly tend and more in terms of being constitutive of plural and diverse global systems, the West remains the pivot around which these ideas circulate.

The challenge posed to modernization theory by the approach of multiple and alternative modernities has some significance in its own terms, but it is much less fundamental than its advocates suppose. The basic premise of theorists of multiple and alternative modernities, of questioning the dominant assumption of convergence and its corollary idea of one trajectory to modernity, is an important qualification to modernization theory. What is significant in its omission, however, is the failure to address adequately the way in which the West remains the point of reference. Further, in maintaining its focus on the internal dynamics of *separate* civilizations and the inability to take a point of view *other* than from the West, the comparative approach exacerbates the problem of Eurocentrism by ignoring and even actively excluding (through its use of ideal types) the connected and entangled histories that constitute the basis of an adequate understanding of the global context of sociohistoric processes. As Arif Dirlik (2003) argues, by identifying 'multiplicity' with culture, the idea of multiple modernities seeks to contain challenges to modernity by conceding the possibility of different ways of being modern, but doing nothing to address the problems with the conceptualization of modernity itself. Delinking our understandings of sociohistoric processes from a European trajectory and focusing not only on the different sources and roots but also on the ways these interacted and intersected over time would provide us with a richer understanding of the complexities of the world in which we live and the historical processes that constitute it. There is a need, as Sanjay Subrahmanyam has argued, to address these *interconnections* as opposed to reifying the entities that are supposed to be connected.

Postcolonial Theory and the Coloniality/Modernity Paradigm

Two traditions that have been most significant in reconceptualizing understandings of modernity have been those associated with postcolonial theory and the coloniality/modernity school of thought. Since the 1960s and 1970s, knowledge claims in the social sciences and humanities have been under pressure from the rise of subaltern positions and an explicitly recognized politics of knowledge production. If we now understand dominant approaches as Eurocentric, for example, it is because of new voices emerging in wider political arenas and in the academy itself. The end of colonialism as an explicit political formation has given rise to understandings of postcoloniality and, perhaps ironically, an increased recognition of the role that colonialism played in the formation of modernity. Postcolonial and decolonial scholarship has been integral to the opening out and questioning of the assumptions of the dominant discourses and, following Boaventura de Sousa Santos (2007), arguing for the possibility of other knowledges. This is also developed by Sujata Patel (2014) who argues for the contestation of colonial modernity within and by the global south in order to establish other understandings of modernity.

Such arguments have been most successful in their challenge to the insularity of historical narratives and historiographical traditions emanating from Europe or what are seen as northern epistemologies (see Spivak, 1988). This has been particularly so in the context of demonstrating the parochial character of arguments about the endogenous European origins of modernity in favor of arguments that suggest the necessity of considering the emergence of the modern world in the broader histories of colonialism, empire, dispossession, and enslavement.

Postcolonial theory, according to Homi Bhabha (1994), attempts to disrupt standard discourses of modernity by shifting the frame through which we view the events of modernity and questioning what we consider those events to be. This is not a version of multiple modernities, in that it does not offer

an alternative modernity to be placed alongside those already seen to be existing. Rather, it calls on us to interrogate the conceptual paradigm of modernity, as it has commonly been understood, from the perspectives of those Others usually relegated to the margins, if included at all. These Others, usually constituted as being outside modernity, exist in both the global south and the global north. Their perspectives are now taken to be central to understanding modernity conceptually.

The task, as Bhabha (1994) puts it, is to take responsibility for the unspoken, unrepresented pasts within our present and, through an understanding of them, reconfigure what it means to be modern. This reconsideration does not relegate difference simply to cultural expression, but calls upon that difference to make a difference to the narratives of modernity already in place. The issue, according to Bhabha (1994), is more about reinscribing 'other' cultural traditions into narratives of modernity and thus transforming those narratives – in both historical terms and theoretical ones – rather than simply renaming or reevaluating the content of these other 'inheritances.'

The meaning of modernity, according to Bhabha (1994), does not derive from a foundational event in the past, but from its continual contestation in the present. This negotiation calls into question both the conditions with which modernity is typically associated and those who lay claim to it. In naming ourselves as modern, as Bhabha (1994) suggests, one moves from the periphery to the center and, in the process, transforms the understanding of 'modernity' from which and about which one speaks. This resonates with the work of the coloniality/modernity school of thought, which is linked to world-systems theory as well as scholarly work in development and underdevelopment studies.

The theoretical distinction – coloniality/modernity – was first articulated by Anibal Quijano (2007). He argues that with the sixteenth-century conquest of the lands that we now call Latin America emerged a new world order which ended up encapsulating the whole planet. This coloniality of power, expressed through political and economic spheres, he continues, was strongly associated with the coloniality of knowledge (or of imagination), articulated as modernity/rationality. The modernity that Europe takes as the context for its own being is, he suggests, so deeply imbricated in the structures of European colonial domination over the rest of the world that it is impossible to separate the two: hence, modernity/coloniality. This understanding enables critique of the European paradigm of modernity/coloniality to be more than a simple refutation of modernity. Rather, it presents a more complicated and more complex definition of it.

The elaboration of the mutual coconstitution of modernity/coloniality and the extension of the timeframe of modernity back to the fifteenth century are two of the key contributions made by Quijano (2007) to its reconceptualization. Both aspects radically challenge standard notions of modernity. The temporal dimension is stretched back from the eighteenth century to the fifteenth century and the spatial dimension is expanded from northern Europe, specifically France and Britain, also to include southern Europe, specifically Spain and Portugal, and Latin America. Acknowledging these shifts establishes colonialism as the precondition for the development of (ideas of) modernity and all subsequent understandings of modernity have to take into account the conditions of its emergence.

Walter Mignolo (2007) builds on Quijano's earlier theoretical work and, in particular, further elaborates his conception of modernity/coloniality in the context of the work of epistemic decolonization necessary to undo the damage wrought by both modernity and by understanding modernity/coloniality only as modernity. Mignolo (2007) argues for a process of 'delinking' that is both an epistemic delinking from the rhetoric of modernity and a practical delinking – that is, a struggle to break free – from the logic of coloniality. His project of 'delinking' points to the need to change the terms (concepts) as well as the content (histories) of the conversations on modernity/coloniality that enables the histories and thought of other places to be understood as prior to European incursions and to be used as the basis of developing connected histories and sociologies of encounters through those incursions.

Mignolo (2007) argues for the importance of recovering earlier histories, that is, histories prior to colonization, from which to articulate both alternative possibilities of living and modes of resistance to the logics of modernity/coloniality. Shifting the historical frame of significant events from Europe to other parts of the world, and prior to European contact, necessitates a historiography of global history cognizant of colonialism and coloniality. This rewriting does not involve the inscription of a new form of universal modernity, but rather, for Mignolo (2007), a differently understood *pluri*versal form, where local histories and their narratives of colonization and decolonization can connect through shared experiences and create new ways of being modern and understanding modernity.

Conclusion

In standard histories of sociology, modernity, or the modern world, is seen to come into being as a consequence of the 'twin' revolutions – the French and the Industrial. In more critical work, it has also long been associated with the processes of dispossession, enslavement, colonialism, and imperialism. This understanding of the coconstitution of coloniality–modernity, and the general silence around this, is central to any proper appreciation of the history of the concept.

Modernization

Abstract

The most widespread use of political modernization is that of a deep-seated transformation of a nonmodern political system in a posttraditional modern political order with key characteristics such as rationalization of authority, differentiation of new political functions, mass participation, capacity building, establishing equality as a major guideline, and a sequence, in which economic development is conducive to cultural changes that make individual autonomy and democracy increasingly likely. There are many routes that lead toward modernity, and modernization has been associated with outcomes of different quality. The diversity of political modernization gave rise to major revisions of classical modernization theories, such as the substitution of 'complex' theories for 'simple' modernization patterns, and the amendment of classical modernization theory by the theory of modern 'risk society.'

Political modernization has three different, yet related, meanings. In political discourses, it refers to successful and enduring adaptation of the political structures of a country in a way which secures system maintenance and political innovation. Political modernization may also be used for the transformation of a previously nonmodern or semimodern society to a higher level of socioeconomic and political development. In the vocabulary of the social sciences, the most widespread use of political modernization is that of a transformation of a nonmodern, mostly traditional political system in a posttraditional political order.

The defining characteristics of political modernization in the latter sense embrace above all (1) "rationalization of authority" (Huntington, 1966: p. 378), i.e., the replacement of traditional political authority by single, secular, national political authority; (2) differentiation, i.e., a "process of progressive separation and specialization of roles, institutional spheres, and associations in the development of political systems" (Coleman, 1968: p. 397); (3) the expansion of popular involvement and participation in the polity; (4) the establishment of equality as a key norm, comprising above all adult citizenship, universalistic legal norms, and the prevalence of achievement criteria in recruitment to political and administrative roles, and, in the case of democratic modernization; and (5) a "human development sequence" (Inglehart and Welzel, 2005), in which economic development tends to substitute self-expression values for survival values and makes individual autonomy and democracy more likely.

Routes to Political Modernization

Many routes lead to political modernization. The most ancient route has been that of Western Europe. That trajectory was mainly derived from, or overlayered with, conflicts of class. A second route was opened through creation of overseas migration to the New Worlds in North America and Australasia. Political development in the 'colonial zone' (Therborn, 1995: p. 6) marked a third path to political modernization. A fourth route has resided in those cases, in which a policy of defensive modernization, initially adopted mainly for the purpose of strengthening the 'power state,' was ultimately conducive to democratizing the polity of the country, such as in Japan and South Korea. A fifth trajectory to political modernization has taken place in Central and Eastern European postcommunist countries. That path involves two modernization processes: the replacement of a planned economy by a mixed economy or a market economy, and the substitution of a democracy for an autocratic regime. Whether political change in countries such as Tunisia, Lybia, and Egypt since 2010 ('Arab Spring') represents a sixth route to modernity, representative of an 'Islamic type of modernity,' remains questionable because nonsecular forces and survival values have remained powerful and massive restrictions of political rights and civil liberties have continued to prevail in these countries.

Simple and Complex Patterns of Political Modernization

In a stylized fashion, one can distinguish between theories of 'simple' and 'complex' patterns of political modernization. Theories of simple political modernization patterns regard modernization as a relatively uniform, homogeneous, stable, linear, and irreversible process. This family of theories also expects more benefits than costs from political modernization. In contrast to this, theories of complex modernization patterns conceptualize political modernization as a heterogeneous, pluralistic, precarious, crisis-ridden, nonlinear, and reversible process. Moreover, these theories also focus attention on side effects, unintended consequences, and massive social costs associated with political modernization. According to this view, political modernization does not necessarily generate a fairer and a more efficient political system. Moreover, theories of complex modernization also emphasize path-dependent patterns of social and cultural change. According to this view, the cultural heritage of a society – for example, the heritage of catholic or protestant religion, Islam, or communism – will have a lasting impact on political culture and will be conducive to the emergence of 'families of nations' (Castles, 1993), such as the Scandinavian countries, the English-speaking nations, Post-Communist Europe, and the Islamic world.

The shift in focus from simple to complex patterns of modernization mirrors that political modernization may be more loosely coupled with successful socioeconomic development and high levels of political performance than predicted in simple modernization theories. For example, economic and social development may be associated with political modernity or a polity with strong premodern characteristics, good governance or low levels of governance, and democratization or persistence of semidemocratic or nondemocratic regimes. The persistence of nondemocratic regimes is exemplified by economically advanced oil-exporting states in the Middle East. Furthermore, democratic modernization can be achieved not only at a relatively advanced stage of socioeconomic development, but also on a far lower level. With development, Przeworski and Limongi (1997: p. 178) have argued, democracy can flourish in poor countries. This view is testified both by democratization of former Third World countries in the 1970s, 1980s, and 1990s and the maintenance of democracy in these states. Finally, a relatively advanced stage of socioeconomic development does not necessarily preclude the breakdown of democratic modernization as the collapse of the Weimar Republic in Germany in 1933 demonstrates (Wehler, 2003).

Determinants of Successful Paths to Political Modernization

The plurality of routes to political modernity mirrors a wide variety of factors that are conducive to, or inhibit, the effort to modernize a country. Among the factors that facilitate political modernization, sustained economic growth plays a major role, while the level of economic development is, beyond a certain threshold, not decisive. But sustained economic stagnation or a long period of economic decline is likely to block every route to political modernization. Moreover, the chances for successful political modernization tend to be higher in ethnically relatively homogeneous countries, and lower in more heterogeneous states. However, appropriate techniques of compromise building, such as consociationalism, can bridge sharp ethnic differences. The determinants of political modernization outcomes include political action on the part of collective and individual actors as well as actor constellations. For example, a distribution of power between traditional and modernization-oriented elites biased toward the latter is of importance. Large protest movements demanding political modernization are also relevant players. Supportive factors include a manageable sequence in which major system-development problems, or 'crisis of development,' generic to the political modernization processes are encountered, such as the formation of national identity and political legitimacy, a certain degree of centralization of political power, participation, social and political integration, and the use of government power for effective allocation and distribution of goods. Furthermore, international factors make a difference. Democratic political modernization, for example, flourishes within the context of a democracy-friendly international environment. The driving forces of successful political modernization include, as R. Inglehart's and C. Welzel's analysis of survey data from the Worlds Values Survey and the European Values Study suggest, a political culture in which 'self-expression values' prevail over 'survival values' (Inglehart and Welzel, 2005, 2009). 'Self-expression values' give priority to postmaterialist values and are conducive to attributes that are crucial to democracy, such as 'a culture of trust and tolerance,' participatory political orientations and preference for individual freedom. In contrast to this, the dominance of 'survival values' in a society's value system, i.e., values that give "top priority to economic and physical security and conformist social norms"(Inglehart and Welzel, 2009: p. 40) impedes political modernization.

Nonreflexive and Reflexive Modernization

Like other complex and dynamic processes, political modernization generates different types of outcomes – intended and unintended ones. Political modernization may result in different roles of the polity, such as 'polity dominance,' 'polity dependence,' or 'polity autonomy' (Coleman, 1968: p. 399), and it may be associated with consolidated or defective types of (Croissant and Merkel, 2004). Moreover, political modernization may result in a higher level of economic development, an advanced welfare state, and better governance, but it has also been associated with weak economic growth, limited social protection, and 'destructive dimensions' (Eisenstadt, 2011: p. 1612), such as repression, exclusion, wars, and generation of risks for future generations, for example, high ecological costs. The ambivalent tendencies of modernization manifest themselves most clearly in the theory of 'risk society' (Beck, 1986) and the theory of 'reflexive modernization' (Beck et al., 1997). According to these theories, the process of 'modernization of modernization' of former industrial societies has resulted in a dramatic increase of 'manufactured risks' (Giddens, 1999) in economically advanced countries.

Theories of reflexive modernization are important contributions to the study of advanced social and political systems. However, they share a weakness with other relatively general theories: They tend to disregard the large degree of variation, which according to comparative politics and comparative political economy, characterizes the structures of modernity, the nature of 'manufactured risks,' the political consequences of classical and reflexive modernization, and the political capacities to cope with effects and side effects of modernization processes.

Modernization and Modernity in History

Paul Nolte, International University, Bremen, Germany

© 2015 Elsevier Ltd. All rights reserved.

This article is reproduced from the previous edition, volume 15, pp. 9954–9961, Elsevier Ltd., with revisions made by the Editor.

Abstract

The article analyzes 'modernization' and 'modernity' as key concepts in history and the social sciences, from their origins in eighteenth- and nineteenth-century sociology and historical thinking through the late twentieth century and especially after 1945. It describes the high tide of classical modernization theory after World War II and its subsequent usage in different historiographical traditions (particularly the United States and Germany). The article then deals with the critique, both theoretically and normatively grounded, of modernization theory since the 1980s, and the resulting shift toward concepts of (cultural) modernity and its contradictions. However, in recent years, a reappraisal of macrosociological modernization theories has occurred, for example, in the use of concepts such as 'reflexive modernization' or in the idea of a plurality of modernities in postcolonial theory.

Modernization and modernity have emerged, particularly after World War II, as key concepts in Western social science. They refer to a long-term process of change primarily in the Western world, but also outside the Euro-Atlantic hemisphere, by which traditional agrarian societies are transformed into the complex systems of industrial (and possibly democratic) societies typical of the late nineteenth and twentieth centuries ('modernization'). As a result of this process, societies and cultures develop a typical set of characteristics (e.g., in personality structure, organizations and institutions, and systems of belief and symbolic expression) that set them apart from older, premodern types of sociocultural systems ('modernity'). For many centuries, scholars have described and tried to explain – and also to intellectually support – the process of modernization in terms of concepts such as social differentiation, rationalization, or economic development. From the 1950s onward, such concepts have been more explicitly formulated as social-scientific theories of Western development, especially in American social science, but spreading very influentially from there to the academic cultures of other Western countries ('modernization theory'). As modernization describes a process of change in history, research in this field has proved to be a very important, almost paradigmatic area of cooperation and exchange between the social sciences and the discipline of history, and a particular branch of sociology called 'historical sociology' has centered around the concept of modernization as Westernization of societies, mostly during the past three to five centuries. Since the 1980s, modernization theories have increasingly been attacked – and often rejected – for their normative, Western-biased implications. At the same time, however, the concept of modernity has become more prominent in attempts at defining twentieth-century culture and its ambiguities. In addition, the 1990s have witnessed a renaissance of modernization theory in a reformulated framework of cultural skepticism and multiculturalism, an intellectual trend that is also significant for new attempts at 'bringing society back in' as the pendulum swings back from a radical emphasis on 'culture' in history and other social sciences.

Concepts of Modernity and Modernization before 1945

The term 'modern' (Latin *modernus*) has been in use since the fifth century AD to distinguish the 'new' or 'current' from the 'old' or 'antique' (Latin *antiquus*), especially as a means of describing and legitimizing new institutions, new legal rules, or new scholarly assumptions (Gumbrecht, 1978). Thus, the term 'modern' has been carrying some normative implications from its very inception to claim modernity for oneself meant a depreciation of the old or traditional and the attempt to win distance from it. In a very general sense and up to our own time, the concept of 'modern/modernity' is anchored in an attempt at defining one's own 'present' by differentiating it from the past. The conflict over the primacy of the new, or modern, over the old, or antique, has paradigmatically been fought out in the French *Querelles des anciens et des modernes* in the late seventeenth century; after the 'Querelles,' the superiority of the modern over the classic, or traditional, has rarely been fundamentally in doubt in the Western tradition of thought. The emphasis on the 'modern' gained additional support in the eighteenth century, when the enlightenment shifted historical thinking from cyclical to linear-progressive models. Since then, and especially after the American and French revolutions, the modern world was considered a world that in a radical and emphatic way was open into the future, a future that was to be attained by a natural progression of the cultural state of society.

In the wake of this fundamental shift, 'modern' was no longer just an opposition to the old or classic but came to be regarded as the long-term process of change that was called 'modernization' in twentieth-century social science. In that sense, the so-called 'stage theories' of historical development brought forward most impressively by writers of the Scottish enlightenment (Smith, Ferguson, and others) can be seen as the first explicit and scientific modernization theories; at the same time, they were founded on the claim of a Western superiority over colonial or 'savage' societies. During the nineteenth century, when developmental and progressivist thinking became a dominant pattern, the idea of modernization became

closely connected to evolutionary theory; the process of modernization was considered an ever-advancing evolution of Western traits leading toward a highly industrialized, rational, and bureaucratic social organization. This link to evolutionary theory prominently figured in the modernization theories of the mid-twentieth century but has lost much of its appeal since then. Probably, the most prominent, and certainly the most influential, variant of nineteenth century (evolutionary) modernization theories has been Karl Marx and Friedrich Engels' historical-materialist theory of Western development. It provided a consistent view of the long-term processes of change, identified mechanisms of social change and progress (namely, the evolution of the productive forces and the subsequent change of social (class) relations), and it underscored the importance of the transition to a capitalist industrial economy in the nineteenth century. In doing so, it provided a model for later modernization theories, be they Marxist or anti-Marxist, and at the same time, established a powerful 'master narrative' of Western history which patterned much historical writing in the twentieth century.

The most important bridge between those 'classical' theories of modernization (from the enlightenment to Marxism) and the more specifically scholarly scientific approaches to modernization that developed in the mid-twentieth century was built by the founding fathers of modern sociology around the turn of the century, especially by Emile Durkheim and Max Weber. Weber's idea of modernization as occidental rationalization, empirically grounded in his political sociology and his comparative sociology of religion, proved enormously influential in systematic and historical sociology – from Talcott Parsons to Reinhard Bendix and S.N. Eisenstadt – as well as in history. Weber succeeded in combining scope and historical depth with analytical concepts; he evaded the pitfalls of Marxism by giving weight to cultural, religious, and intellectual factors as well as material factors in his view on the specificity of modern Western development. Although the high tide of classical Weberian sociology, and of the adoption of Weberian categories in historical writing, may have been over since the late 1970s or 1980s, his thought remains influential in recent attempts at reformulating the ideas of modernity and modernization, as Weber is now seen less as an advocate of progress and rationalization and more as a shrewd observer of the deep ambiguities of modernization and modern life.

Modernization and Modernization Theory in the Social Sciences after 1945

After World War II, 'modernization theory' in a more limited, very specific sense emerged in the context of American social science, and American postwar political culture in general. With the 'American century' and the vision of a 'Pax Americana' reaching its climax, economic, political, and social development elsewhere in the world was increasingly viewed in the perspective of progressive Americanization that would, in the end, lead to a homogeneous system of modern industrial societies. The modernization of the West, and the USA in particular, was regarded a model for the future development of 'Third World' countries, their agrarian societies, and authoritarian political structures. The optimistic mood of social-scientific theories in this vein, their sometimes crude and simplistic assumptions about modernization, and their somewhat intellectually 'imperialist' stance toward non-European cultures have been much criticized since the late 1960s. In some areas of cultural theory and cultural history, they have been treated with contempt or, at best, with disregard. However, one should not ignore the fact that in the 1950s and 1960s, modernization theory marked an important step in the professionalization of concepts of social change and development and in the thinking about 'modernity' in general. Also, concepts of modernization developed in sociology and political science often radiated beyond the boundaries of their disciplines and proved very influential in other disciplines such as history.

The approaches of modernization theory between the 1950s and 1970s need not be described here in detail (for an overview and literature, see Lerner et al., 1968), but it may be useful to mention some fundamental concepts and assumptions, especially insofar as they inspired empirical work in historical sociology or history proper. The classical post-1945 modernization theory crystallized at a time when structural–functional theory in sociology stood in high regard, and when social and cultural problems were often discussed in terms of a theory of social systems. Harvard sociologist Talcott Parsons best epitomizes this approach; like many others, he attempted to link the somewhat static assumptions of functionalism with more dynamic Weberian concepts of rationalization and evolutionary change in Western history (see, e.g., Parsons, 1966). American modernization theory mostly concentrated on the transition from 'traditional society' to industrial capitalism in the economy and on the transition to democracy and mass participation in the realm of politics. For Western societies, this implied a strong focus on the nineteenth century, a time period which at that time also became increasingly important in the work of historians in many countries. While quantitative approaches in modernization theory were rarely applied in empirical historical studies, qualitative analytical concepts like theories of economic growth (e.g., Walt W. Rostow, Alexander Gerschenkron) and of political modernization, especially of state formation and nation-building (e.g., Karl W. Deutsch), proved attractive for historians interested in problems of social and institutional change.

In modernization theories of the 1950s and 1960s, a dichotomy of 'tradition' and 'modernity' often figured prominently; sociologists and political scientists established catalogs with typical features of 'traditional' societies (e.g., agrarian, localistic, and homogeneous) and contrasted them with features of 'modern' societies (e.g., urban, centralistic, and heterogeneous). Though this seemed to confirm a static, even ahistorical bias in modernization theory, the traditional–modern dichotomy, which in many respects traces back to Ferdinand Toennies' distinction between *Gemeinschaft* and *Gesellschaft*, became a widespread analytical tool in history and historical sociology in the 1960s and 1970s. Concepts such as this, focusing on the transition from tradition to modernity through a series of crises which modernizing societies had to undergo, proved attractive to historians who were interested in the history of revolutions or in the emergence of participatory democracy. They also triggered a wave of empirical work in

historical sociology between the late 1950s and the early 1970s in which historical processes of transition to modernity were analyzed, as in Neil Smelser's application of Parsonian theory to English industrialization (Smelser, 1959). Other scholars made use of Weberian concepts of comparative change in Western and non-Western (e.g., China and Japan) societies (see, e.g., Eisenstadt, 1973; Moore, 1966). This line of research has never been completely cut off, but it grew thinner and, in the 1980s and 1990s, stood under an ever larger shadow of cultural theory and anthropology, that is, of disciplines and approaches which fundamentally questioned the assumptions of macrosociological Western-oriented modernization theory.

Modernization and Modernization Theory in Historical Work

Historians in many Western countries have found theoretical concepts on modernity and modernization increasingly interesting since the 1950s, and especially during the 1960s and 1970s. There are several reasons for this. First, the postwar modernization theories were more than an intradisciplinary project; they served as an expression of a general mood and intellectual climate – of progress, of Western success, etc. – that did not leave academics from other disciplines, particularly in the humanities, unaffected. Second, the discipline of history at that time was very much in search for new approaches, for new master narratives, which would be able to support the ongoing broad expansion of history into the fields of social and economic history. At the same time, more historians became interested in comparative or international history, and modernization theory offered ways and concepts of pursuing such approaches. Third, the period of the 1950s to the 1970s was characterized by an intense cooperation between historians and social scientists; historians were looking for theoretical models in sociology and political science, while on the other hand, students of these disciplines attempted to treat their subjects – the formation of societies, the building of nation-states, or the emergence of party systems – with more historical depth (Kocka, 1996). In a very general sense, in which 'modernization theory' is not understood as a coherent theoretical concept, but more as a diffuse historical 'plot structure' of societal modernization, economic progress, and political democratization, it may indeed be said that "The quintessential professionalized historical discourse of the first postwar decades was modernization theory" (Applegate, 1999: p. 1162). However, this statement could also be made for much of nineteenth- and early twentieth-century liberal ('Whig') historiography; and even in the 1960s or 1970s, it was always a small minority of historians who made explicit use of social-scientific concepts of modernity and modernization in their empirical work. Also, national cultures and traditions of historiography diverged very much in that regard. While Anglo-American 'empiricist' culture generally worked as a barrier against the intrusion of theoretical concepts in historical writing, German scientific culture, with its strong traditions of fundamental theorizing, encouraged the adaptation of such concepts. American (USA) and German historiography can serve as examples for a somewhat closer look at the role of modernization theory in the discipline of history.

The United States of America

The fact that the USA was the seedbed for the most influential modernization theories after 1945 might induce the assumption that concepts of modernization have been widely adopted by American historians, but that is not the case, at least not with modernization theories in a more limited social-scientific meaning of that term. It is true that American historiography had a long tradition of 'progressivist' interpretation of its nation's history, even before the rise of the 'Progressive Historians' at the beginning of the twentieth century. Indeed, it is safe to say that a progressivist impulse constituted the very beginnings of American national historiography in the early nineteenth century (e.g., George Bancroft). After the nineteenth-century idea of progress had lost much of its original persuasion, modernization theory offered a somewhat more sophisticated replacement. Yet, as Dorothy Ross has maintained, "Its ideological use, reductionism, and historical determinism made historians wary of it from the start," and "Only few historical studies have in fact openly claimed modernization as the theoretical basis of their work" (Ross, 1998: p. 93). On the other hand, central assumptions of modernization theory often tacitly informed 1950s historiography, particularly in the then predominant school of 'consensus history,' which sought to establish an image of America as a country of conflict-free modernism. While it can be argued that in this perspective America had never been truly 'traditional' as European feudal societies were influential consensus historians such as David Potter drew on social-scientific notions of a modernizing American character; Potter (1954), for example, explicitly referred to David Riesman's theory of a transition from 'inner-directed' to 'other-directed' man. Similarly, it is very common among American historians to point to a fundamental dichotomy between *Gemeinschaft* and *Gesellschaft* and to use this distinction for describing modernization processes or historical developments that lead in the direction of a growing social complexity and differentiation. In what can be regarded as one of the most important historical case studies on American modernization, Robert Wiebe has argued for a fundamental change in the organizing principles of American society in the decades around 1900, a change which he describes as the transition from 'island communities' with their communal values to a technological and industrialized order shaped by the bureaucratic mentality of a new professional middle class (Wiebe, 1967). Still, American historians have generally been hesitant in explicitly using modernization theories from sociology or political science; even more so since around 1980, when the culturalist turn in the humanities generated additional skepticism about master narratives of progress and linear development.

Germany

In parts of the West German historical profession during the 1960s, an intellectual climate very favorable to the reception of ideas on modernization in general, and of social-scientific theories of modernization in particular, developed. It was part of a broader, international tendency toward social and economic history in the postwar decades, at the expense of the more traditional political and diplomatic history, but probably

even more important, were factors specific to German history and to the German political situation after the Third Reich. As a younger generation of academics began to orient themselves toward the West, especially the USA, they opened up for new theoretical and interpretative concepts brought forward by American social science, and modernization theory with its broad perspectives on comparative social change was regarded as one of the most intellectually promising programs (Wehler, 1975). The experience of fascism and the Holocaust in Germany lead many historians and social scientists to ask for long-term developments in German history responsible for the German inclination toward authoritarian government in the twentieth century, and the answer was found in failures of the modernization process in Germany especially since the mid-nineteenth century, after the revolution of 1848 and Bismarck's unification of Germany.

In a book enormously influential with the general public and professional historians alike, sociologist Ralf Dahrendorf eloquently elaborated the notion of Germany as a country being unable to adapt its institutional structures and its mentalities to the necessities of a 'modern' society. Paradoxically, Dahrendorf argued only the results of the National Socialist regime finally threw Germany into modernity (Dahrendorf, 1965). In the following two or three decades, much of nineteenth- and twentieth-century German social history was influenced by an interpretive framework of a German *Sonderweg* into modernity, that is, a specific course of German history characterized by deficient modernization, with the transition to democracy and to modern civil values lagging behind other Western countries (see Kocka, 1999). As German social historians, more so than their colleagues in the UK, France, or the USA, were interested in theoretical concepts of social history and social change, they also undertook efforts at explicitly using social-scientific modernization theories in their empirical work and in their writing of history. The most ambitious and widely discussed project in this vein is Hans-Ulrich Wehler's multivolume *Deutsche Gesellschaftsgeschichte*, a broad attempt at synthesizing modern German history with a focus on social and economic structures and with a discussion of Germany's specific modernization problems as its red thread and intellectual core (Wehler, 1987–1995).

In Wehler's work as well as in German history in general, however, Weberian concepts of modernity and of comparative social change increasingly superseded, especially since the 1980s, concepts from contemporary American social science. A Weberian perspective seemed to offer more historical depth, going beyond the assumption of a sharp break between the 'traditional' and the 'modern' world in the nineteenth century. Even more important, as naively optimistic versions of modernization theory became less persuasive in the 1980s, Max Weber's emphasis on the ambiguities of modernization, on the complicated web of gains and losses called forth by the Western rationalization process, looked more attractive to many historians. In this perspective, the failures of German history culminating in the Third Reich were not simply caused by a modernization lag but were, at least in part, inherent problems and results of modernity itself. This fundamental shift in the assessment of modernity and modernization, however, was not restricted to Germany but can be traced as a general trend in historical and social-scientific thought since the 1980s.

From Modernization to Modernity: Critique and Reappraisal since the 1980s

Since around 1980, postwar concepts of modernization and modernity have come under heavy attack, in history as well as in the social sciences and humanities in general. Within the overall trend toward a more critical, or skeptical, appraisal of modernization in history, it is important to distinguish several strands, even if they often overlap in historiographical practice.

In many Western countries, the history of what in English-language usage is called the 'early modern' period, that is, the history of the sixteenth to eighteenth centuries has witnessed an unprecedented expansion since around 1970 – particularly in Germany and the USA, perhaps less so in the UK and France (where the history of this period is called *histoire moderne*). As social historians have taken a much closer look at societies which according to social-scientific modernization theory are 'traditional' and 'static' societies, it appears that Western societies before the industrial and democratic revolutions were not so traditional after all but quite dynamic and expansive. This has been a heavy blow to theoretical and historical assumptions about a sharp break between traditional and modern societies that presumably happened (in North America and Western Europe) in the decades around 1800. It has thus prompted historians to ask for 'modern' structures in earlier times and for continuities of 'tradition' in the industrial period, with the effect of further questioning historiographical models of modernization as teleological evolution and linear progression. Among interpretations of long-term change in Europe since the Middle Ages, German sociologist Norbert Elias' theory of the civilization process proved very stimulating among historians from the late 1970s, perhaps because his perspective on civilization is compatible with both 'optimistic' and 'pessimistic' viewpoints on modernization (Elias, 1976). A 'pessimistic' reading of Elias focuses on the process of growing 'discipline,' self-control, and oppression, in many ways similar to Michel Foucault's understanding of modernity that became influential at about the same time. Especially in French and Italian historiography on the early modern era, modernization was now regarded as a strategic project of literate elites for the suppression of popular culture and ordinary people (see, for example, Muchembled, 1978).

Along with the 'culturalist turn' in the humanities, with the emergence of cultural anthropology as a paradigmatic discipline for the whole field of humanities, the core meaning and content of the concept of 'modernity' has shifted from economy to culture. When historians, and scholars in general, talk about modernity, they now hardly ever refer to the economic modernity that originated in the European and North American industrial revolutions, as was the case between the 1950s and 1970s. Instead, they refer to the idea of a specifically modern culture, that is, to the idea that modernity is defined by certain attitudes and belief systems, by models of cultural expression as they have been shaped, for example, by the mass media. It is important to recognize that the idea of modernity as culture is by no means new; after all, the *Querelles*

of the seventeenth century were about culture, and a cultural approach to the understanding of modernity is central to writers like Baudelaire in the nineteenth century as well as to many neo-Marxian strands of thought in the twentieth century, from Gramsci to Adorno and Habermas. In recent years, the current experience of a new information and knowledge revolution has directed attention toward the role of science and knowledge in the formation of modern culture; again, it can be said that modernity now appears to be less a product of economic forces and more a product of systematic knowledge, its reproduction, and its application through the emergence of a system of scientific disciplines.

Two further changes go along with this shift from economy to culture. First, instead of using the term 'modernization' (and hence emphasizing a processual change), many cultural theorists and historians now prefer to talk about 'modernity' or 'modernism' because they have become uncertain whether the notion of the modern and the idea of progress and development should be linked closely to one another, as was the case with the 'older' modernization theories. Second, although 'modernity' may be used very widely to characterize cultural innovation in different historical times, there is a clear propensity to concentrate on the twentieth century and define the twentieth century as an age of modernity – whereas former modernization theories, as has been pointed out before, tended to see the nineteenth century as the crucial breakthrough period of the modern. Particularly in American and in German historiography, the beginning of the twentieth century is now regarded as a period of fundamental change in society and culture, as a time when modern, urban mass society as we still today know it, first crystallized. Instead of pointing to industrial production forces, historians have come to view the beginnings of a consumer society as a strong indicator for modernity (see, e.g., Dumenil, 1995).

Contradictions of Modernity

It has already been mentioned that postwar modernization theories have come under attack for their sometimes all too simplistic constructions, for their bias on Westernization, and for their claim that modernization unmistakably effected economic or political 'progress.' As historians have started to ask for the 'social costs' of modernization, for the experience of the 'losers' in this process, the balance sheet began to look different. However, the assumption now is often not just that modernization had some ambivalent consequences or side effects but that modernization and modernity in themselves carry some dangerous anticivilizatory and eventually catastrophic potentials. Like the concept of 'cultural modernity' sketched before, the notion of inherent contradictions of modernity is very much grounded in the historical experience of the twentieth century: namely, in the experience of dictatorship and totalitarianism, of mass murder and ethnic cleansing. Those dark sides of twentieth century history can no longer be persuasively explained as abnormal aberrations from an otherwise successful path of modernization; modernization and modernity rather look janus faced; they bear in them the potentials for both civilization and barbarism, and there is no way of neatly separating those two sides. In the 1980s, twentieth-century German history provided the first important paradigm for this interpretation. In research about Weimar and Nazi Germany, it turned out that modernism, or the quest for modernization, could be politically reactionary in both its intentions and its effects (Herf, 1984). During the 1990s, a fierce debate was fought among German historians over the question of the ostensible 'modernity' of National Socialism (see Frei, 1993). At the same time, the Holocaust perpetrated by Nazi Germany came to be seen as a paradigm for general contradictions of the modernization process; it hinted at contradictions not only apparent in German history but also in the history of Western civilization as a whole. Sociologist Zygmunt Bauman in a widely received book maintained that "The Holocaust was born and executed in our modern rational society" (Bauman, 1989: p. X). Hence, the Holocaust poses a question not just to German history but also to 'Western civilization' as a whole. The Holocaust, in other words, in the 1990s often serves as a metaphor for the potentially murderous implications of modernity and modernization in the Western trajectory.

From Modernity to Postmodernism?

Instead of reformulating modernization into modernity and pointing at its contradictions, a second way of dealing with the widespread discontents with the postwar modernization theories in the 1980s was to leave the 'modern' behind and claim a new era of 'postmodernism' and the reign of postmodern intellectual principles in the humanities and social sciences. In the fields of literature, political science, and cultural criticism, the impact of the postmodernist impulse has been enormous, but historical discourse has been much less influenced by it in all major Western countries. Although some claims about the 'end of history' or the 'end of modernity' resonated among historians, hardly, any serious attempts were undertaken to conceptualize 'postmodernity' as a distinct epoch in the context of historical periodization. Nor have there been many efforts at describing certain social or cultural phenomena of the twentieth century under the heading of postmodernism in a way that was comparable to the notion of a modernist culture that emerged during the same time.

As a methodological and theoretical concept, postmodernism was somewhat more successful. Borrowing from literary and cultural theory, historians in the late 1980s and 1990s discussed whether the time-honored claims of historiography to objectivity and factuality could still be sustained and whether the narrative master plots of history – of which 'modernization' was one of the most important – should be followed in historical writing at all (for a fair, yet critical discussion of these issues, see Appleby et al., 1994). In its resistance against the modernization master narrative of history, the postmodernist impulse shared some of the more general skepticism about linear-progressive theories of history and social development, but it soon turned out that any contemporary reformulation of modernization concepts, however critical it was considering the ecological crisis, ethnic mass murders, or the challenges of multiculturalism, would be best advised to stick to the category of modernity. For to claim a new, postmodern era did not eventually promise to be helpful in the attempt at explaining the often bitter consequences of

modernity and modernization, an attempt that most historians and social scientists still find necessary.

Toward a New Theory of Modernization?

While historians are still debating the end of modernization and the demise of the grand narrative of modernization in historical writing, the concept of modernization has witnessed a remarkable renaissance in sociology since the mid- to late 1980s (Mergel, 1997: p. 203). The experiences of ecological crisis and catastrophe on the one hand and of economic globalization and a worldwide diffusion of cultures on the other hand have made sociologists think anew about societal change on a macrolevel, on differences between tradition and modernity, and on the possible course and direction of social evolution at the turn of the millennium. The enormous dynamics of change in contemporary society is now being conceived as an equivalent to the major transition described by older modernization theories as a shift from agrarian to industrial societies. As the classical form of industrial societies is coming to an end, Ulrich Beck has argued, it is becoming 'tradition' itself, a tradition that is now undergoing a process of second-degree rationalization (Beck, 1986). Industrial society was only 'half-modern' and is now being dissolved in a process called 'reflexive modernization' because the modernization process is becoming reflexive by being reproduced and pushed forward in scientific and public discourses about the problems generated by it.

The concept of reflexive modernization has also been suggested by Anthony Giddens in what he calls an "institutional analysis of modernity with cultural and epistemological overtones" (Giddens, 1990: p. I; cf Beck et al., 1994). For Giddens, the dynamism of modernity derives from (1) a separation of time and space ('time–space distanciation'); (2) the 'disembedding' of social systems in an increasingly globalized world; and (3) a reflexive ordering and reordering of social relations, affected by continual inputs of knowledge (Giddens, 1990: pp. 16–17). In this second stage, or 'radicalized modernity,' social change is not any longer comparable to a car controlled by the driver but is like a 'juggernaut' – "a runaway engine of enormous power which, collectively as human beings, we can drive to some extent, but which also threatens to rush out of our control and which could rend itself asunder" (Giddens, 1990: p. 139). In Giddens' view, globalization is not simply a spreading of Western culture and economy throughout the world; yet he firmly remains committed to the idea of modernity as a Western project.

Other authors, who argue from a 'postcolonial' political and epistemological perspective, are more skeptical about the Westernness of the ongoing modernization process. As traditional spatial boundaries disappear, cultures overlap and identities become hybrid creatures with different cultural backgrounds. The result, then, is not a continuation of Western modernity but a new plurality of modernities ('multiple modernities') without a clear priority of the West (see Appadurai, 1996).

However, as a common denominator of all these approaches, an emphasis on the spatial reordering of social relations and on the complicated relationship between globalization and local identity formation emerges. The new theories about reflexive and global modernization are important because they shift attention from a somewhat static notion of cultural modernity back to modernization as a process in time, and that is, among other things, what makes them particularly promising in the field of history. On the other hand, their understanding of historical processes, especially their assessment of social change in the period of the first (industrial) modernization and prior to it, is often superficial and sometimes naïve. Historians are just beginning to discuss the new macrosociological theories of modernization, and perhaps a fruitful dialog between historians and sociologists will develop in the near future. The idea of modernization has weathered many storms and changed its appearance, but it seems that it still offers an indispensable clue to the historical and sociological analysis of long-term changes in society and culture.

Abstract

Sociological theory views modernization as a macroprocess of transition from traditional society to the society of modernity. More specifically, the main sociological theories of modernization are based on the ideas of evolutionism, functionalism, and diffusionism. Attention is also paid to the theoretical conceptualization of modernization processes in non-Western societies, which can be explained by the interaction of endogenous and exogenous factors. Within the framework of scientific discourse and the public consciousness, theory of modernization is sometimes questioned as a view of a progressive development of the world. Today, the global spread of modernization is more adequately theorized in terms of historical and sociocultural dynamic shifts from institutionalized, vertically integrated forms of social solidarity to network forms and social movements. This view of modernization as a communication phenomenon that involves the changing ways of interaction and media use highlights its self-reflexive nature, showing how modernization can only gain an access to itself by a series of partial and conflicting descriptions.

Defining Modernization

Overall, modernization is understood as a macroprocess of transition from traditional society to the society of modernity, leading to the appearance of "modes of social life or organization which emerged in Europe from about the seventeenth century onwards and which subsequently became more or less worldwide in their influence" (Giddens, 1990: p. 1).

Today, the concept of modernization is understood in three different meanings: (1) as the internal development of Western Europe and North America relating to the European New Era; (2) as a process by which countries that do not belong to the first group of countries aim to catch up with them; and (3) as processes of evolutionary development of the most modernized societies (Western Europe and North America), i.e., modernization as a permanent process, carried out through reform and innovation, which today means a transition to a postindustrial society.

1. Speaking of the genealogy of the word 'modern,' German philosopher Jürgen Habermas notes that it was first used in Europe at the end of the fifth century in order to differentiate between the received official status of the Christian present and the pagan Roman past (Habermas, 1985a). In subsequent periods, the content of this understanding changed, but only the Enlightenment and Romanticism gave it the meaning that it has today. Since then, that which promotes objective expression of spontaneously renewing the actuality of the spirit of the time is considered contemporary and modern.

As a result of the accelerated development during the Modern times in Europe, a unique modern civilization was formed which radically differed from traditional societies. A fragmented political system of Europe created preconditions for the emergence of industrial capitalism. Modernity originated in Western Europe due to the formation of the Protestant work ethic, the market economy, bureaucracy, and legal systems. In Western Europe, the large-scale process of modernization – the transition from a traditional (preindustrial) society to a society of modernity – took several centuries, genealogically dating back to the industrial revolution in England, and the strengthening of the bourgeoisie as it gained political power from the revolutions in Britain (1640–42), the US (1776), and France (1789).

Usually, three periods of modernization are distinguished: the first period – the end of the eighteenth century to the beginning of the twentieth century; the second period – the 1920s–1960s; and the third period – the 1970s–1990s. According to some social theorists, e.g., Ulrich Beck and Anthony Giddens, we are living a period of late modernity, its consequences having only intensified (Beck, 1998; Giddens, 1990). For Beck, for instance, the so-called simple modernization resulted in industrial society; when continued, the modernization of industrial society leads to the creation of a risk society.

Some authors believe that (contemporary) modernity cannot be completed at all. Thus, the Senegalese sociologist Samir Amin argues that 'modernity' is unfinished, but it opens the doors to the unknown. Modernity is inherently incompletable, but it involves a sequence of diverse forms, which contradicts the society at each moment of its history (Amin, 2000: pp. 581–622).

Modern society includes four basic institutions: a competitive democracy, a market economy, a welfare state, and mass communication. A market economy is the basis of an autonomous civil society, which overcomes all boundaries and creates an open society. Unlike other more detailed studies of cultural anthropology in traditional societies, modern societies are based on the principles of suffrage law, universalization of civil rights, the institutionalization of social change, secular culture and secularism, urbanization, the autonomy of subsystems, rationalization, dominance of the market economy, bureaucratization, professionalization, mass literacy and mass media, and the growth of social and professional mobility.
